BEFORE THE DEPARTMENT OF THE TREASURY
ALCOHOL AND TOBACCO TAX AND TRADE BUREAU
WASHINGTON, D.C.

In re: BELLION SPIRITS, LLC'S PETITION FOR HEALTH CLAIMS UNDER 27 C.F.R. §§ 70.701, 7.54(e)	)	**TTB DOCKET No. _____** **PETITION FOR HEALTH CLAIMS**

PETITION FOR HEALTH CLAIMS UNDER 27 C.F.R. § 70.701 & 7.54(e)

Bellion Spirits, LLC and Chigurupati Technologies (collectively "Bellion" or "Petitioners"), by counsel and pursuant to 27 CFR §§ 70.701 and 7.54(e), hereby submit this petition for health-related statements concerning the effect of NTX® in distilled spirits or beverages. NTX® is a proprietary blend of glycyrrhizin,[1] mannitol,[2] and potassium sorbate.[3] As discussed below and in the materials attached, when NTX® is infused into alcoholic beverages, it renders them safer, i.e., less toxic, than counterparts that do not contain NTX®. NTX® reduces the adverse effects of alcohol on the liver and on DNA. Thus, NTX® lessens certain deleterious effects caused from consumption of alcohol. Accordingly, Petitioners hereby request that the Alcohol and Tobacco Tax and Trade Bureau ("TTB") declare, via rulemaking or through the exercise of enforcement discretion, that the use of the Petitioners' proposed health-related statements concerning the hepatoprotective and DNA-protective effects of NTX® in the labeling and advertising of wines, distilled spirits, and malt beverages is permissible. The health claims

[1] Glycyrrhizin is an extract of licorice root.
[2] Mannitol is a sugar alcohol.
[3] Potassium sorbate is commonly used as a food preservative.

requested through this petition facilitate informed decisions concerning consumer health when purchasing and/or consuming alcoholic beverages. The health claims identified in this petition are truthful and non-misleading, supported by peer-reviewed scientific literature and human clinical studies. By giving consumers an ability to distinguish between alcoholic beverages that are less toxic than traditional counterparts, consumers may choose the healthier alcoholic beverage and, as a result, experience greater health and wellness than would otherwise be the case.

Petitioners' proposed health-related statements appear in section III below. Attached hereto, and incorporated in this petition, are the following supportive materials: (1) Expert Report of Dr. Sidney Stohs, Ph.D., FACN, CNS, ATS, FAPhA; (2) Expert Report of Dr. Harry G. Preuss, MD, MACN, CNS; (3) Stohs Curriculum Vitae; (4) Preuss Curriculum Vitae; and (5) scientific literature and studies supportive of the NTX technology.[4]

TABLE OF CONTENTS

[4] Bellion submits its confidential and proprietary scientific data "Confidential" under 5 U.S.C. § 552(B)(4).

I. Interests of the Petitioners

Bellion Spirits, LLC is the independent bottler and distributor of Bellion brand Vodka. Its principal place of business is Bellion Spirits LLC, One Harmon Plaza, Suite 805, Secaucus,

NJ 07094. Bellion Spirits was founded to pioneer innovation in the alcohol beverage industry, through the introduction of functional alcoholic beverages, which generally retain the customary characteristics of alcoholic beverages, while reducing or mitigating the unwanted negative effects, like damage to the liver, genetic injuries, and oxidative stress. Bellion's scientific and commercial goals focus on the education of consumers concerning the detrimental effects of alcohol consumption, along with the advantages of functional beverages or spirits that aid consumers in making smarter, safer, and healthier choices. Bellion's objectives include the distribution of products and technologies that help to educate consumers about the chemical interactions of alcohol in the body (both positive and negative). Bellion has coined the phrase "Functional Spirits" as a description of the benefits or protective properties conveyed through its technology, as described more fully below in this petition.

Chigurupati Technologies Private Ltd. is solely a Research & Development institution founded with the objective to "aid in the evolution of mankind." Its principal place of business is Plot No. 512/m/1. Road No. 31 Jubilee Hills, Hyderabad, 500033, Andhra Pradesh, India. By focusing on research and development, Chigurupati Technologies develops and leverages innovations that later provide beneficial health products for consumers globally, thus encouraging a physical and philosophical consumer evolution. Chigurupati Technologies depends on its ability to convey scientific literature and facts to consumers and businesses in association with its technologies.

Chigurupati Technologies Private Ltd. developed and owns a proprietary blend of three generally recognized as safe ingredients combined through a proprietary process and sold under the name "NTX." Those three ingredients are Glycyrrhizin Acid, D-Mannitol, and Potassium Sorbate. "NTX" is thus an ingredient in Bellion Vodka that Bellion purchases from Chigurupati

Technologies. Studies commissioned by Chigurupati Technologies reveal that "NTX," when infused into liquor, yields a protective effect on the human liver during alcohol consumption, lessening the adverse effect of alcohol on the liver. Heretofore that information has not appeared on the label, in the labeling, or in the advertising for alcohol containing products sold in the United States. NTX® also adds flavor and smoothness to the vodka drink. Bellion Vodka has not promoted the use of NTX for health purposes, but seeks to convey the liver and DNA protective effects of alcohol containing NTX® through this instant petition.

II. Procedural Background

In 2014, Bellion petitioned the TTB through the COLA process and requested approval for the use of Bellion's "NTX" designation on labeling. That designation reveals the presence of Bellion's proprietary blend in vodkas. In a letter dated December 17, 2014, the TTB informed Bellion it would send two pending COLAs[5] for Bellion Vodka back to the applicant, Frank-Lin Distillers Products, Ltd. ("Frank-Lin"), with a "Needs Correction" notification because the labels' referenced "NTX." According to the TTB, the acronym "NTX" was a misleading health claim.

At the time, Bellion's labeling included the following descriptive phrase as the statement of composition: "Vodka Infused With Natural Flavors." The label included the following statements:

For over 600 years, vodka has been made the same way.
No longer. Infused with NTX, Bellion changes vodka forever.

• Vodka Evolved • Infused With Natural Flavors • Created With NTX •

[5] The labels' TTB ID numbers are 1425001000403 and 14227001000056.

Bellion's labels did not explain or define the acronym "NTX." Both of Bellion's label applications, however, identified "NTX" as a fanciful name. One COLA submission provided the following explanation:

> NTX = NEW TECHNIX (OR NEW TECHNIQUES). THIS IS A BREAKTHROUGH COMBINATION OF INGREDIENTS AND PROPRIETARY TECHNIQUES THAT REMOVES THE UNDESIRABLE ATTRIBUTES [TASTES] COMMON IN MANY VODKAS AND PROMOTES SMOOTHNESS AND ROUNDNESS AND MOUTHFEEL BEYOND WHAT NORMAL FILTRATION AND MULTIPLE DISTILLATIONS CAN DO. WORLDWIDE PATENT AND TRADEMARK PROTECTION IS IN PROCESS. BRAND NAME, LOGO AND GRAPHICS MAY REPEAT; LOT NUMBER(S) MAY APPEAR/CHANGE.

According to the TTB, reference to "NTX" was an implied specific health claim in violation of 27 C.F.R. § 5.42(b)(8). The TTB determined that extraneous information not present on the Bellion label (e.g., in scientific publications elsewhere) touted the health benefits of "NTX." TTB asserted that "NTX" was an implied claim relating to Naltrexone, a prescription drug that was approved for the treatment of alcohol dependence, and "[t]he use of the drug NTX to treat alcohol dependency, as well as publicly available studies claiming that NTX has beneficial effects for patients with elevated liver enzymes, would be likely to reinforce the health claim . . . and cause further confusion about the term 'NTX.'" The TTB produced no consumer perception or survey data in support of its COLA denials.

On January 15, 2015, Bellion Spirits, L.L.C. appealed the TTB COLA denial through 27 CFR § 13.25. That appeal asserted that the TTB's censorship of the "NTX" labeling information violated the First Amendment of the U.S. Constitution because, inter alia, the TTB had no factual or legal bases to censor basic information related to product composition and ingredients. The

parties informally resolved the COLA disputes and, in April 2015, the TTB approved separate COLA applications for Bellion Vodka labels that referenced "NTX."[6]

Now, through this instant submission, Bellion petitions the TTB for use of nine (9) specific health claims under 27 CFR § 7.54(e) related to the NTX® ingredients contained in Bellion Vodka.

III. Requested Action

Petitioners hereby request that the TTB rule that alcoholic spirit beverages that contain NTX® may bear one or more the following health-related statements in its labeling, advertising, or promotional speech:

- NTX® provides antioxidant and anti-inflammatory support;
- NTX® helps protect against, i.e., reduces, alcohol-induced oxidative damage to the liver;
- NTX® helps maintain normal liver enzyme production and function;
- NTX® supports normal liver defenses and regenerative mechanisms;
- NTX® reduces the risk of alcohol-induced liver diseases, including fibrosis and cirrhosis;
- NTX® helps maintain normal liver functions;
- NTX® helps protect DNA from alcohol-induced damage; and
- NTX® reduces alcohol-induced DNA damage.

[6] The labels' TTB ID numbers are 15091001000076 (approved) and 15091001000077 (expired). Previously, the TTB had approved a label that was identical to the labels at issue in the appeal (TTB ID number 13294001000173). Frank-Lin voluntarily surrendered that label on July 31, 2014, however, at the request of the TTB. Two other labels (TTB ID numbers 13052001000468 and 13051001000241) were surrendered in 2014 because the applicant, Covington Spirits, L.L.C., no longer bottled Bellion Vodka.

Those health-related statements are accompanied by the following, prominently placed disclaimer:

> NTX® does not protect against all health risks associated with moderate and heavy levels of alcohol consumption, including, but not limited to, motor vehicle accidents, high blood pressure, stroke, cancer, birth defects, psychological problems, and alcohol dependency. Do not consume alcohol if: you are younger than the legal drinking age; you are pregnant or may become pregnant; you are taking medicine that can interact with alcohol; you have a medical condition for which alcohol is contraindicated; you plan to drive; or you cannot restrict your drinking to moderate levels. If you consume alcohol, only consume it in moderation. "Moderation" means up to one drink per day for women and up to two drinks per day for men.

The above-listed health-related statements are truthful and non-misleading. The disclaimer language is reasonable and adequate to properly identify the remaining risks inherent in alcohol consumption. As discussed below, the above-listed health claims are protected speech under the First Amendment to the United States Constitution.

IV. Legal and Statutory Framework

The provision of truthful and non-misleading health information is indispensable to informed consumer choice. The need for accurate health information at the point of sale is no less important in the alcoholic beverage context as it is in the food and dietary supplement context. *See, e.g., Pearson v. Shalala*, 164 F.3d 650 (D.C. Cir. 1999). Unlike the Federal Food and Drug Administration, the TTB has yet to adopt a cogent and workable regulatory regime for the evaluation of health-related statements. *C.f.* 21 CFR § 101.70 (articulating procedure and elements required for health claim petition). To determine whether a health claim satisfies Section 27 CFR 7.54, petitioners must have a full and fair opportunity to present all supportive science. The adequacy of that science must be evaluated in context with the benefit sought to be achieved.

Bellion submits this instant petition for agency action in lieu of (or in conjunction with) the COLA process, in part, because the TTB's existing regulatory framework concerning health claim petitions is inadequate and insufficient to provide constitutionally required protection for truthful and non-misleading health information on the label, in the labeling, and in the advertising of alcoholic beverages.

A. TTB's Extant Framework Involving Health-Related Statements

The Federal Alcohol Administration Act authorizes the Secretary of the Treasury to promulgate regulations concerning the labeling and advertising of alcoholic beverages, including regulations that are intended to prevent consumer deception and prohibit the use of misleading statements, irrespective of falsity. *See* 27 U.S.C. § 205(e)-(f).

In 2003, the TTB issued regulations for the use of health claims and health-related statements in the labeling and advertising of wines, distilled spirits, and malt beverages. *See* 68 Fed. Reg. 10076 (Mar. 3, 2003) (Health Claims and Other Health-Related Statements in the Labeling and Advertising of Alcohol Beverages); 27 C.F.R. § 4.39(i) (labeling of wine); *id*. at § 4.64(i) (advertising of wine); *id*. at § 5.42(b)(8) (labeling of distilled spirits); *id*. at § 5.65(d) (advertising of distilled spirits); *id*. at § 7.29(e) (labeling of malt beverages); and *id*. at § 7.54(e) (advertising of malt beverages). Those regulations attempted to balance the speaker's First Amendment right to label and advertise products through truthful and non-misleading scientific information and the public's right to be informed of the significant health risks associated with alcohol consumption.[7]

[7] The agency was motivated apparently by the well-established scientific link between moderate alcohol consumption (notably red wine consumption) and a reduced risk of coronary heart disease. *See, e.g.*, 68 Fed. Reg. 10076, 10082-83 (Mar. 3, 2003). The TTB had refused to permit health claims associated with red wine, despite the general agreement in support of that claim by the scientific and medical fields.

Under TTB's health claim regulations, alcoholic beverage labels and advertisements may not contain any health-related statement that is untrue in any particular or tends to create a misleading impression as to the effects on health of alcohol consumption. *See id.* at §§ 4.39(h)(2), 4.64(i)(2), 5.42(b)(8)(ii), 5.65(d)(2), 7.29(e)(2), 7.54(e)(2). For purposes of the TTB's regulations, a "health-related statement," means:

> [A]ny statement related to health . . . and includes statements of a curative or therapeutic nature that, expressly or by implication, suggest a relationship between the consumption of alcohol, distilled spirits, or any substance found within the distilled spirits, and health benefits or effects on health. The term includes both specific health claims and general references to alleged health benefits or effects on health associated with the consumption of alcohol, distilled spirits, or any substance found within the distilled spirits, as well as health-related directional statements. The term also includes statements and claims that imply that a physical or psychological sensation results from consuming the distilled spirits, as well as statements and claims of nutritional value (*e.g.,* statements of vitamin content). Statements concerning caloric, carbohydrate, protein, and fat content do not constitute nutritional claims about the product.

Id. at §§ 4.39(h)(1)(i), 4.64(i)(1)(i), 5.42(b)(8)(i)(A), 5.65(d)(1)(i), 7.29(e)(1)(i), 7.54(e)(1)(i). Additionally, a "specific health claim," is "a type of health-related statement that expressly or by implication, characterizes the relationship of the distilled spirits, alcohol, or any substance found within the distilled spirits, to a disease or health-related condition." *Id*. at §§ 4.39(h)(1)(ii), 4.64(i)(1)(ii), 5.42(b)(8)(i)(B), 5.65(d)(1)(ii), 7.29(e)(1)(ii), 7.54(e)(1)(ii). Examples of implied specific health claims include the following: "statements, symbols, vignettes, or other forms of communication that suggest, within the context in which they are presented, that a relationship exists between distilled spirits, alcohol, or any substance found within the distilled spirits, and a disease or health-related condition." *Id*.

Thus, the TTB has extended its definition of "health claims" to encompass nearly any statement that suggests a positive benefit for the human body from consumption of alcohol. The

TTB's definition of "health claim" is more expansive than similar interpretations by sister agencies like the FDA. *See* 21 U.S.C. §343(r)(1)(B) (defining a health claim, for purposes of the FDCA, to mean a claim that "characterizes the relationship of any nutrient . . . to a disease or a health-related condition . . .").

If the health-related statement conveys a misleading impression, the TTB may require a prominent disclaimer or other qualifying statement for the purpose of dispelling the misleading impression. *See, e.g.*, 27 C.F.R. § 5.42(b)(8)(ii)(A). Under the TTB's regulations, a specific health claim is misleading unless it: (1) is truthful and adequately substantiated by scientific or medical evidence; (2) is sufficiently detailed and qualified with respect to the categories of individuals to whom the claim applies; (3) adequately discloses the health risks associated with both moderate and heavier levels of alcohol consumption; and (4) outlines the categories of individuals for whom any alcohol consumption poses risks. *See, e.g., id*. at § 5.42(b)(8)(ii)(B)(2). That information must appear as part of the specific health claim on a label, and, in advertising, as prominent as the specific health claim. *See id*. The TTB has never produced a consumer survey or impact study that determined consumers' level of understanding concerning health-related claims and alcohol consumption.

B. The TTB Must Implement a Constitutional Regulatory Framework for Evaluation of Health Claim Petitions

Unlike the Federal Food and Drug Administration, the TTB has yet to issue workable regulatory procedures and criteria for the evaluation of health-related statements. That regulatory deficiency creates hardship for petitioners, like Bellion, by denying them a well-defined regulatory avenue within TTB jurisdiction that will ensure allowance of constitutionally protected speech on the labels, in the labeling, and in advertising of alcoholic beverages. The limited scope and applicability of extant TTB labeling and advertising regulations precludes the

sponsorship of health claim petitions that could satisfy the elements of the TTB's regulations in, for example, Section 5.42(b)(8). As discussed below the process available to advertisers and labelers fails under the First Amendment.

In prior meetings between Bellion and TTB staff members in July 2014, the TTB conceded that its health claim procedures were inadequate and regulations concerning same were dead letters. Rather than perform its administrative review, the TTB expressed its intent to transfer health claim petitions to the FDA for review—a procedure that would violate administrative procedure. "Agency action taken without statutory authorization, or which frustrates the congressional policy which underlies a statute, is invalid." *See Yankton Sioux Tribe v. Kempthorne*, 442 F.Supp.2d 774, 784 (D.S.D. 2006). The FDA lacks jurisdiction or authority to interpret the TTB's regulations. *See Am. Library Assn. v. FCC*, 406 F.3d 689, 702 (D.C. Cir. 2005) (an agency does not possess plenary authority to act within a given area simply because Congress has endowed it with some authority to act in that area); *see also* 5 U.S.C. § 706(2)(C) (under the APA, agency action must be set aside and deemed unlawful where the agency acts "in excess of statutory jurisdiction, authority, or limitations, or short of statutory right").

Congress tasked the TTB with the regulation of spirit products, which includes exclusive authority to regulate their labeling and advertising. *See* 27 U.S.C. §§ 201, *et seq.* The FDA lacks statutory authority to regulate alcoholic spirits that are within the TTB's purview. *See Brown-Forman Distillers Corp. v. Mathews*, 435 F. Supp. 5, 8 (W.D. Ky. 1976) ("it was Congress' intention to place exclusive jurisdiction in BATF with respect to regulating labeling of alcoholic beverages."). Nothing in the FAA Act grants the TTB authority to delegate its

administrative functions or responsibilities to the FDA, and the FDA similarly lacks primary authority to regulate the labels and advertising of alcoholic spirits. *Id.* at 12.

i. TTB's Mandatory Label Reviews (COLAs) Are Inadequate

Regardless of whether a label bears a health-related statement, the TTB must generally preapprove wine, distilled spirit, and malt beverage labels.[8] *See* 27 C.F.R. §§ 4.50-4.52 (wine); *id*. at §§ 5.55-5.56 (distilled spirits); *id*. at §§ 7.40-7.42 (malt beverages). To obtain the TTB's approval, alcohol producers may apply for a Certification/Exemption of Label/Bottle Approval ("COLA"). The TTB will reject the application if the label fails to comply with applicable regulations or is otherwise deficient. For instance, the TTB will decline to approve an application if the label bears a misleading health-related statement in violation of the regulations discussed above. The TTB evaluates health-related statements on a case-by-case basis during its label reviews. *See id*.

Although the TTB will examine health-related statements that appear on labels of alcoholic beverages during its standard review, the "COLAs Online" process is not equipped to receive information necessary to demonstrate that a particular-health related claim is substantiated (to wit, that the claim is truthful and non-misleading, and supported by reliable scientific evidence). For instance, the only type of label attachments included within a filed COLA application include JPEG and TIFF file formats that use only RGB color mode. *See* TTB, COLAs and Formulas Online FAQs.[9] Moreover, the paper COLA application, TTB F 5100.31,

[8] Certain changes to labels that the TTB has previously approved may be made without obtaining a new certification/exemption of label/bottle approval ("COLA") from the TTB. *See*, TTB, *List of Allowable Changes to Approved Labels*, *available at* http://www.ttb.gov/labeling/allowable_revisions.shtml#completeList (last accessed Mar. 31, 2016).

[9] *Available at* http://www.ttb.gov/faqs/colasonline.shtml (last accessed April 5, 2015).

which can be submitted in lieu of an electronic application, includes no exceptions or provisions that allow submission of detailed scientific information related to health statements on labels or labeling.

Even if the COLA process permitted the submission of information regarding a health-related statement that appears on the label of an alcoholic beverage, the TTB could, theoretically, leave applicants buried within "corrective" processes inherent to the COLA review process. The system of administrative appeals is not designed (nor efficient enough) to prevent significant constitutional injury or alleviate the burdens of the TTB's prior restraint of health claim language. As explained below, a deprivation of First Amendment rights, even for minimal periods of time, constitutes an irreparable constitutional injury. *Elrod v. Burns*, 427 U.S. 347, 373–74 (1976). To the extent Bellion is precluded from communicating its truthful scientific information, it suffers an irreparable constitutional injury.

The COLA process is also too narrow to achieve the proper review of claims that would be used beyond labels or labeling. The COLA process pertains solely and exclusively to content appearing on spirit labels or labeling. That approval process has no relationship to advertising statements, or promotional content that may appear beyond the "label" of an alcoholic product. Thus, the COLA process would provide inadequate and inefficient relief for Bellion here. Petitioners are not requesting the use of specific health-related statements on a specific label, but, rather, they seek permission to include the proposed health-related statements throughout their labels, advertising, and promotional content. Moreover, Bellion would choose from among the various health claims subject to approval when designing or implementing labeling changes. Bellion should not be required to independently clear health claims through the COLA process

when such approval can most efficiently and pragmatically proceed through one health claim petition, the instant petition.

ii. TTB Advanced Review of Advertisements Is Inadequate

Although the TTB must preapprove alcoholic beverage labels, its regulations do not require preapproval of alcoholic beverage advertisements, including those that contain health-related statements.[10] The TTB, however, may review advertisements that appear in various media (e.g., online, print, or broadcast) on a case-by-case basis, either on its own accord or in response to complaints it receives about specific advertisements. Like labels, the TTB reviews alcoholic beverage advertisements on a case-by-case basis. *See id*. at § 7.54(a), (e)(2)(i) (malt beverages); *id*. at § 5.65(a)(1), (d)(2)(i) (distilled spirits); and *id*. at §4.64(a)(1), (i)(2)(i) (wine).

An alcoholic beverage advertiser faces serious risk when it includes a health-related statement in advertisements. For instance, several years prior, the TTB targeted an advertisement for alcoholic beverages that contained ingredients associated with non-alcohol energy drinks on the grounds that they implied that ingestion of the extra ingredients would result in a stimulating or energizing effect or enable consumers to drink more of a product without feeling the effects of alcohol in violation of the TTB's advertising regulations. Rather than have an advertiser bear the risk that the TTB will initiate enforcement action for use of a health-related statement in an advertisement, the TTB must provide a clear pathway for premarket claims approval.

[10] Alcoholic beverage industry member may, voluntarily, pre-clear advertising with the TTB.

iii. Bellion Has the Right to Petition the TTB for Health Claims

The First Amendment guarantees the right to petition government for redress. *Am. Bus. Ass'n v. Rogoff*, 649 F.3d 734, 738 (D.C. Cir. 2011) ("The right to petition is cut from the same cloth as the other guarantees of [the First] Amendment, and is an assurance of a particular freedom of expression"). The right "extends to [petitioning] all departments of the Government, including administrative agencies and courts." *Id.* (quoting *Cal. Motor Transport Co. v. Trucking Unlimited*, 404 U.S. 508, 510 (1972)). That pathway is particularly important here, where Bellion's commercial speech might otherwise subject it to liability absent TTB's preapproval of health claim language.

Administrative agencies are obliged by the Administrative Procedures Act (APA) to respond to petitions of the kind here presented. *See* 5 U.S.C. § 555(e) (requiring a response to a petition along with a "statement of the grounds for denial").

Consistent with the constitutional requirement for prompt relief in matters trenching upon free speech, federal courts have routinely excused the exhaustion doctrine in the administrative context where, as here: (1) the unexhausted remedy would plainly be inadequate; (2) a constitutional claim remains at issue even after theoretical exhaustion occurred; (3) the relief requested cannot be granted by the agency (e.g., through a facial challenge to agency regulations); (4) exhaustion would be futile; and (5) the petitioner would otherwise suffer irreparable harm if unable to secure immediate judicial review. *See, e.g., Dawson Farms, LLC v. Farm Serv. Agency*, 504 F.3d 592, 606 (5th Cir. 2007); *Ace Prop. & Cas. Ins. Co. v. Fed. Crop Ins. Corp.*, 440 F.3d 992, 999–1000 (8th Cir. 2006); *McBride Cotton & Cattle Corp. v. Veneman*, 290 F.3d 973, 980 (9th Cir. 2002). In other words, to the extent the TTB refuses to promptly and timely respond to this petition, relief in the district courts will be appropriate to prevent Bellion's

imminent loss of First Amendment rights through TTB's prior restraint on truthful health claim language. It is the law that TTB prohibits health statements on the labels, in the labeling, and in the advertising of alcohol containing products, unless it acts to allow or approve of the statements. Hence, there is an immediate and all-encompassing prior restraint on precisely the claims Bellion seeks in this petition, which restraint can either be lifted promptly by TTB or judicial review is warranted under the common exceptions to the exhaustion doctrine.

The TTB's health claim regulations and review process described in Sections 7.54(e) and 5.42(b) have erected a total ban on health related claims in the marketplace, in part, because the TTB has yet to implement the administrative process or structure needed to consider a properly noticed health claim petition. The TTB conceded that point in prior rulemaking: "TTB agrees that the regulations make it difficult to present a substantive health claim (for example, one involving cardiovascular benefits associated with moderate alcohol consumption)…" *See* Final Rule, *Healht Claims and Other Health-Related Statements in the Labeling and Advertising of Alcohol Beverages*, 68 Fed. Reg. 10076 (Mar. 3, 2003). The lack of meaningful review procedures effects an unconstitutional prior restraint of health claims in the marketplace, and renders action on this instant petition necessary. TTB may not shirk its constitutional duty under the First Amendment to ensure that truthful health statements are not suppressed; consequently, in the face of the present petition, it must review it and it must do so promptly.

C. Bellion's Proposed Health Claims Are Truthful, Non-Misleading, and Satisfy the TTB's Health Claim Regulations

Bellion has proposed the use of eight (8) health claims that accurately reflect the scientific evidence concerning NTX® technology. Those statements are truthful, substantiated by scientific and medical evidence; are sufficiently detailed and qualified with respect to the

categories of individuals to whom the claim applies; adequately disclose the health risks associated with both moderate and heavier levels of alcohol consumption; and explain the categories of individuals for whom any alcohol consumption poses risks.

The claims sufficiently describe the categories of individuals to whom the claims apply. Bellion's functional spirit infused with NTX® is designed for use by all lawful consumers of alcoholic beverages. The ill-effects of alcohol use are common knowledge and sufficiently known by the TTB and consumers. According to the World Health Organization's most recent data, the harmful use of alcohol is among the top five risk factors for disease, disability, and death. *See* Vladimir Poznyak & Dag Rekve, *Global Status Report on Alcohol and Health 2014*, World Health Org., p. 2.[11] The long-term effects of alcohol consumption can damage most organs of the human body. *Caan, Woody; Belleroche, Jackie de, eds. (11 April 2002). Drink, Drugs and Dependence: From Science to Clinical Practice (1st ed.). Routledge. pp. 19–20.*

Liver diseases are the predominant health concern associated with alcohol consumption because over time heavy drinking causes the multifaceted disease known as Alcoholic Liver Disease ("ALD"). ALD is characterized by hepatic steatosis or increased fat deposits in the liver. It can cause alcoholic hepatitis, also known as inflammation of the liver, and cellular stress from oxidation of the liver. *See* Aditya Ambade & Pranoti Mandrekar, Oxidative Stress and Inflammation: Essential Partners in Alcoholic Liver Disease, International Journal of Hepatology, Volume 2012 (2012), Art. ID 853175.[12] After prolonged alcohol consumption, ALD culminates in irreversible destruction and scarring (fibrosis) of the liver tissue called

[11] *Available at* http://apps.who.int/iris/bitstream/10665/112736/1/9789240692763_eng.pdf?ua=1 (last accessed April 4, 2016).

[12] *Available at* http://www.hindawi.com/journals/ijh/2012/853175/ (last accessed April 4, 2016).

cirrhosis, which ultimately leads to liver failure. *See Mayo Clinic*, Alcohol Use Disorder: Complications, (July 25, 2015).[13] While it is axiomatic in the ALD context that the more heavily one consumes alcohol—and the greater frequency of drinking—the more likely one is to develop cirrhosis, it should be noted that alcohol tolerance varies from person to person, and for some people one drink a day is sufficient to leave permanent scars on the liver. *See* Jennifer, Robinson, M.D., *Understanding Cirrhosis of the Liver*, WebMD (February 1, 2015).[14] Thus, hepatoprotective effects that limit liver injury are cumulative and likely to benefit moderate drinkers over their adulthood.

The CDC reported 36,427 deaths in 2013 from chronic liver diseases, making it the 12th leading cause of death in the United States. *See* Jiaquan Xu, M.D., Sherry Murphy, B.S., Kenneth Kochanek, M.A., & Brigham Bastian, *Deaths: Final Data for 2013*, Nat'l Vital Statistics Reports Vol. 62 No. 2, 45 (February 16, 2016).[15] That category is broken down into two sections: (1) ALD, accounted for 18,146 deaths; and (2) other chronic liver diseases and cirrhosis, accounted for 18,281 deaths in the United States in 2013. *Id.* The annual inpatient cost for alcohol-related cirrhosis in 2014 was $850 million, and this figure does not account for the unknown millions more spent on outpatient treatments. *See* Lauren Beste, M.D., *Alcoholic Liver Disease*, Gastroenterology & Hepatology, Vol. 12, Issue 1, (January 2016).[16]

Aside from ALD, recent research is demonstrating that alcohol abuse causes the dual-

harms of accumulated DNA damage and alcohol-induced dysfunction to DNA repair, which coalesce into the well-known negative effects of alcohol on the brain, i.e. brain damage. *See* Inna Kruman, George Henderson, and Susan Bergeson, *DNA Damage and Nuerotoxicity of Chronic Alcohol Abuse*, 237 Exp Biol Med 7, 740-47 (July, 24, 2012).[17] Those twin effects of chronic alcohol consumption result in genomic instability and the death of neurons. *Id*. Those destructive effects to the very building blocks of the nervous system are likely the reason that brain damage, including central nervous system degeneration, are associated with chronic alcohol consumption. *Id*.

The ill-effects of alcohol abuse are well-documented. The problems associated with lower levels of alcohol consumption are also documented. *See, e.g.*, National Institute on Alcohol Abuse and Alcoholism, National Institutes of Health, *State of the Science Report on the Effects of Moderate Drinking* (Dec. 19, 2003).[18] Studies suggest that even moderate drinking may contribute to genetic and organ damage. *See, e.g.*, Castelli, E., et al., *Indicators of genetic damage in alcoholics: reversibility after alcohol abstinence*, Hepatogastroenterology, 1999 May-Jun; Vol. 46(27):1664-8; Honor Whiteman, *Young adults "damage DNA" with weekend alcohol consumption*, MedicalNewsToday.com (Jan. 2, 2014);[19] Rendón-Ramirez, R., et al., *Oxidative damage in young alcohol drinkers: A preliminary study*, Alcohol Intn'l Biomed. Journal, 2013 November; Vol. 47(7):501-504. Given the frequency and volume of alcohol consumption in the United States, any product that affords liver and genetic protection during ethanol metabolism is

of considerable health value to consumers nationwide—even if that protective effect merely mitigates, as opposed to eliminates, the damage.

D. Bellion's Health Claims Concerning NTX® Hepatoprotective Effects and DNA Protection Are Truthful and Adequately Substantiated by Scientific and Medical Evidence

The hepatoprotective effect of NTX® is supported by the attached exhibits 1, 3, and 5, and through the more than 100 peer-reviewed scientific publications attached. Those reports, studies, and datasets are herein incorporated into this petition by reference, including the expert reports of Dr. Sidney Stohs and Dr. Harry Preuss. Bellion's experts explain that the requested health claims are supported by the scientific evidence, including product-specific testing, peer-reviewed literature, and animal and in vitro test data.

As discussed above, the harms of alcohol consumption are well documented, and the most common chronic alcohol issue is ALD, which is defined by lesions on the liver ranging from hepatic steatosis to cirrhosis and eventually liver failure. The cascading negative effects of alcohol on the liver are attributable to the mechanisms of alcohol toxicity, which can be summarized in five steps: (1) the metabolism of alcohol to highly toxic acetaldehyde and free radical species; (2) the production of reactive oxygen (ROS) and nitrogen species with resulting oxidative stress; (3) the inflammatory release of cytokines as tumor necrosis factor-alpha and interleukin-6; (4) abnormal lipid metabolism, oxidative DNA damage, formation of protein, and DNA adducts with metabolites of alcohol and acetaldehyde; and (5) ultimately induction of apoptosis or necrosis with subsequent multi-system organ failure. *See* Stohs Rep. at 2.

Biomarkers are biological indicators of the health of an organ. Just as blood sugar elevation is associated with diabetes, common biomarkers can be used to track the progression of

ALD. Elevations of these biomarkers indicate liver disease, while decreases occur as the liver heals. *See id*. at 2-3.

Liver health is generally measured or evaluated through several generally-accepted biomarkers. *See* Preuss Rep. at 3. Those markers indicate disruption of the hepatic function. Scientists evaluate measurements related to the blood serum levels of enzymes such as alanine aminotransferase (ALT), aspartate aminotransferase (AST), gamma-glutamyltransferase (GGT), and alkaline phosophatase (ALP). *See id*. Elevated circulating levels of those enzymes indicate liver injury from excess alcohol intake. *See id*. Moreover, a reduction of those serum levels occur as the liver begins to repair itself. *See id*.

Scientists may look to other biomarkers to evaluate liver function. The hepatic metabolism of alcohol causes excess production of tissue-damaging free radicals and reactive oxygen species (ROS). Markers of oxidative stress and oxidative tissue damage include the production of ROS, the lipid malondialdehyde (MDA), protein carbonyl formation, and DNA damage. Moreover, reductions in glutathione (GSH) levels could indicate intercellular antioxidant and chemoprotectant characteristics in human tissues, in part, because reductions in GSH levels are associated with changes to oxidative stressors. *See id*. at 3-4. Therefore, GSH content is considered an important marker for ROS and free radicals. *See id*. at 4.

The two primary approaches for successful prevention and reversal of liver damage are abstinence from alcohol and appropriate nutritional support. *See id*. Because the vast majority of alcohol users will not abstain, the need to develop safer means of alcohol consumption to reduce the associated morbidity and mortality, as well as the costs to society, are pressing. *See id*. To prevent and treat alcohol-induced liver toxicity the mechanism must disrupt and either inhibit or reverse the five steps of toxicity described above. *See id*. Studies in humans and

animals have demonstrated the hepatic protective effects of NTX® as well as its individual components during acute and chronic alcohol consumption. *See id*.

The two primary ingredients in NTX® are glycyrrhizin and mannitol, which work synergistically to protect the liver from the harmful health effects of alcohol. *See* Stohs Rep. at 4. A randomized, double-blind, placebo-controlled cross-over clinical trial involving 12 human subjects found that NTX® produced a significant decrease in the biomarkers for liver toxicity. *See id*. Another similar test with 31 human subjects showed a significant reduction in biomarkers of liver disease and oxidative liver effects, and the authors indicated that NTX® may be effective at reducing the negative effects of alcohol consumption. *Id*. Furthermore, the synergistic effects of mannitol and glycyrrhizin were demonstrated in a 28 day study in rats where the substances restored the biomarkers of liver function to as high as 80% of normal. *See id*. at 5. In all, over 70 studies show the key components of NTX® produce liver protecting, antioxidant, and anti-inflammatory effects. *See id*. at 7.

Antioxidants and Anti-Inflammation:

The health-related statements regarding the antioxidant, anti-inflammatory effects of NTX® that serve to protect the liver against oxidative damage have been thoroughly substantiated. Human and animal studies alike demonstrate the positive biomarker effects of glycyrrhizin by inhibiting the lipid accumulation in the liver and decreasing inflammatory cytokines, which reduction protects liver function. *See id*. at 8. Several studies have confirmed the tissue protective effects of mannitol, as it is already used as an antioxidant in conjunction with heart bypass surgeries and as an anti-inflammatory in tissue baths following kidney transplants. *See id*. at 9. Fifty human studies and a number of animal studies confirm NTX®'s primary ingredients protect against oxidative liver damage. *See id*. at 12.

A series of animal studies have therefore shown that licorice extract and mannitol favorably decrease reactive oxygen species (ROS) and similar metabolites, lipid peroxidation (MDA formation) as well as carbonyl protein formation secondary to alcohol-induced production. *See* Preuss Rep. at 4. Those studies also show a positive increase in the levels of endogenous antioxidant reduced glutathione (GSH). *See id*. Those key findings concerning glycyrrhizin and mannitol have been corroborated in clinical studies. *See id*. NTX® was shown to decrease alcohol-induced DNA damage in human peripheral lymphocytes. *See id*. at 5. NTX® was also shown to enhance the levels of the enzymes catalase, GPX, and SOD that are responsible for decomposing ROS. *See id*. Thus, NTX® had an ability to protect hepatocytes from the damaging influences of ROS and oxidative stressors. *See id*. Those findings were supported by over thirty published animal, in vitro, and human clinical studies confirming the antioxidant and anti-inflammatory properties of the components in NTX®.

Helps Maintain Normal Liver Function:

The published scientific evidence strongly supports NTX®'s ability to maintain normal or healthy liver function during and after alcohol consumption. Several published human, animal, and cell culture studies revealed that NTX® and its components foster normalization or near-normalization of many liver enzymes, including ALT, AST, GGT, ALP, SOD, GPX, and catalase. *See id*. at 6. NTX®'s proprietary formula (and its components) ameliorate alcohol-induced inflammation. Glycyrrhizin itself has been shown to reduce serum ALT and AST levels in patients with chronic hepatitis by at least thirty-five percent (35%). *See id*.

NTX®'s beneficial effects were documented in a randomized, doubled-blind, placebo-controlled clinical trial involving twelve human subjects through a cross-over model. NTX® provided significant decreases and normalization in the examined biomarkers correlating with

liver toxicity, to wit, ALT, AST, GGT, and ALP. *See id*. Another randomized, double-blind, placebo-controlled cross-over clinical trial involving thirty one (31) human subjects revealed that consumption of alcohol with NTX® significantly reduced the levels of ROS and facilitated development of normal liver enzyme circulating concentrations. *See id*.

The enzymes that are normalized were biomarkers of liver health. When those enzymatic levels decrease, as several randomized double-blind human studies have documented, the ability of NTX® to preclude alcohol toxicity and help maintain normal liver function is substantiated. *See* Stohs Rep. at 13. Several animal studies have shown the defensive and regenerative properties of NTX®, but one in particular on rats actually produced a marked reduction in alcohol-induced liver lesions. *See id*. at 17.

Supports the Liver's Regenerative Mechanism:

The health-related statements regarding reduction of risk for and amelioration of liver diseases including fibrosis and cirrhosis have also been scientifically substantiated. A published meta-analysis summarized the effects of a glycyrrhizin product in 838 patients through 12 randomized trials confirmed that the substance significantly decreased serum levels and improved liver function in alcoholic liver disease cases. *See id*. at 20. NTX® co-administered with alcohol has demonstrated a significant decrease in liver toxicity biomarkers, thereby facilitating increased liver function and regeneration, which reduces the risk of liver diseases like fibrosis and cirrhosis. *See id*. at 22.

Almost fifty published human clinical studies and a substantial number of animal studies have demonstrated that NTX and its specific components (e.g., glycyrrhizin and mannitol) support the liver's normal defense mechanisms against alcohol and other hepatoxins, thus promoting general liver health in those that might drink moderately. A meta-analysis of twelve

randomized human clinical studies evaluated data collected from 838 patients with alcoholic liver disease and concluded that glycyrrhizin significantly decreased serum ALT and AST levels. *See* Preuss Rep. at 8. Another study determined that glycyrrhizin reduced the incidence of liver fibrosis in rats co-administered glycyrrhizin. *See id.* Another double-blind, comparative, cross-over clinical trial examined the effects of alcohol on blood levels of ROS in the absence and presence of co-administered NTX®. *See id*. The results demonstrated that NTX® statistically and significantly reduced the alcohol-induced generation of ROS and ROS metabolites, and further decreased serum lipid peroxidation product MDA, while increasing serum levels of the endogenous antioxidant GSH. *See id*. at 8-9. NTX® also significantly decreased serum protein carbonyl levels. *See id*. at 9. That data demonstrated that NTX® co-administered with alcohol decreased the oxidative tissue damage that would otherwise have been observed during alcohol consumption and metabolism.

Reduces Alcohol-Induced DNA Damage:

NTX® aids in protection of DNA by reducing alcohol-induced damage. Health claims related to that effect are scientifically substantiated. A randomized, double-blind human study revealed that alcohol consumption is damaging to DNA because it damages peripheral lymphocytes, but NTX® significantly reduces the level of damage caused, revealing that it protects DNA. *See* Stohs Rep. at 30. One of the key ways NTX® protects DNA is via its anti-oxidant and suppression of oxidative damage effects. *See id*. Glycyrrhizin has been show to prevent DNA fragmentation and modulated programmed cell death. *See id*. One mechanism of DNA protection was shown in an in vitro model where glycyrrhizin directly bonded to the major and minor grooves and phosphate backbone of DNA, thereby protecting it from damage. *See id*. at 32.

Excess alcohol consumption generally contributes to the production of oxidative damage to DNA and the epigenome. *See* Preuss Rep. at 13. Reactive oxygen species activate or repress epigenetic elements like chromatin remodeling, micro-RNAs, DNA (de)methylation and histone modification. *See id*. at 13-14. Epigenetic changes, even slight alterations, may affect gene expression and could ultimately result in liver disorders. *See id*. at 14. After ingestion, alcohol can form adducts with DNA, inhibiting the formation of various proteins essential for healthy hepatic function. *See id*.. NTX® has been shown through scientific studies and laboratory work to inhibit those negative effects, in part, by restraining the formation of alcohol-induced DNA damage.

In one study involving thirty one (31) subjects in a randomized, double-blind, placebo-controlled cross-over clinical trial, patients challenged with alcohol presented apparent DNA damage in peripheral lymphocytes as measured by single cell electrophoresis comet assay, the cytokinesis-block micronucleus assay, and 8-hydroxy-2-deoxyguanosine formation. When similarly challenged with NTX-infused alcohol, patients presented with a significant reduction in DNA damage. *See id*. In addition, various other studies using human and animal tissues have shown that individually glycyrrhizin and mannitol prevent oxidative DNA damage. *See id*.

Based on the wealth of peer-reviewed literature, animal studies, human clinical test data, and product-specific testing, NTX® and its major components have been shown to reduce DNA damage from DNA single and double strand breaks induced by alcohol and other ROS generating systems in the liver.

Totality of the Scientific Evidence:

The well-documented scientific reports of Drs. Stohs and Preuss present balanced and objective evidence concerning the efficacy of NTX®. The more than 100 studies attached to this

Petition in Exhibit 5 substantiate the health claims requested in section III of this Petition. Significantly, in performing its review of the available scientific evidence under this Petition, TTB must in conformity with First Amendment standards consider all scientific evidence supportive of the requested claims. The TTB must acknowledge that human clinical testing in areas concerning alcohol exposure carries significant health and liability risks that render repeat (or expansive) testing impractical, costly, and perhaps unethical (e.g., long-term studies). The universe of scientific data is therefore limited by those practical considerations. Animal and in vitro models must be considered where supportive of the mechanism of action, or where such studies explain the biophysical or biochemical responses. Animal and in vitro models are often essential to develop or prove causal connections between the test components and a statistically significant effect later observed in human models.

E. NTX® Is Safe and Lawful when Added to Alcoholic Beverages

The TTB has already acknowledged that NTX® may safely and lawfully be added to alcoholic beverages because it has approved the use of NTX® in at least one alcoholic beverage, Bellion branded vodka. Plus, the TTB has authorized the use of mannitol, glycyrrhizin, and potassium sorbate, which are the three ingredients that comprise NTX®, in alcoholic beverages generally, subject to limitations. *See* TTB, *Limited Ingredients: Flavoring Substances and Adjuvants Subject to Limitation or Restriction* (explaining that mannitol, glycyrrhizin, and potassium sorbate may be added so long as they do not exceed 2.5%, 0.1%, and 0.1%, respectively).[20]

[20] *Available at* http://www.ttb.gov/ssd/limited_ingredients.shtml (last accessed April 5, 2016).

Similarly, the federal Food and Drug Administration ("FDA") allows mannitol, glycyrrhizin, and potassium sorbate to be added to foods, which also establishes that NTX® is safe. *See* 21 C.F.R. § 180.25 (approving the use of mannitol as a food additive, and noting that the ingredient is used as an anticaking agent and free flow agent); *id.* at §182.3640 (affirming that potassium sorbate, a chemical preservative, is generally recognized as safe ("GRAS") when it is used in accordance with good manufacturing practice); *id*. at §184.1408 (affirming that licorice and licorice derivatives, including glycyrrhizin, are GRAS when used as flavor enhancers in various foods, including alcoholic beverages).

To further attest to the safety of NTX®, Dr. Stohs' expert report identifies various studies that have evaluated the safety of NTX® and its constituents, and explains that during such studies, no serious adverse events were observed. *See* Stohs Rep. at 33-34.

F. The Proposed Claim Adequately Explains the Health Risks Associated with Both Moderate and Heavier Levels of Alcohol Consumption and Explains the Categories for Whom Any Alcohol Consumption Poses Risks

Consistent with section III *supra*, all Bellion advertising, labeling, and promotional material will feature the following disclaimer that corresponds with the proposed health claims:

> NTX® does not protect against all health risks associated with moderate and heavy levels of alcohol consumption, including, but not limited to, motor vehicle accidents, high blood pressure, stroke, cancer, birth defects, psychological problems, and alcohol dependency. Do not consume alcohol if: you are younger than the legal drinking age; you are pregnant or may become pregnant; you are taking medicine that can interact with alcohol; you have a medical condition for which alcohol is contraindicated; you plan to drive; or you cannot restrict your drinking to moderate levels. If you consume alcohol, only consume it in moderation. "Moderation" means up to one drink per day for women and up to two drinks per day for men.

That disclaimer adequately and succinctly identifies the range of individuals who should not consumer alcohol, including, e.g., those with medical conditions or pregnant women. The claim

identifies the risks of moderate and heavy alcohol consumption that are not addressed through the NTX® technology.

Read in conjunction with the requested health claims, the speech conveyed to consumers precludes any suggestion or impression that alcohol is unequivocally safe to consume. Rather, the claim conveys the truthful and non-misleading impression that alcohol infused with NTX® is healthier than conventional alcoholic beverages, but not a "healthy" product in general terms.

G. The Proposed Claims Do Not Render NTX® a "Drug" Under Federal Law

The TTB has primary jurisdiction over the labeling and advertising of alcoholic beverages that are subject to the federal Alcohol Administration Act ("FAA Act"). *See* 27 U.S.C. § 205(e), (f); 27 C.F.R. Parts 4, 5, 7. The FAA Act applies to distilled spirits and certain wines and malt beverages. *See* 27 U.S.C. § 211(a)(5) (defining "distilled spirit" to mean "ethyl alcohol, hydrated oxide of ethyl, spirits of wine, whiskey, rum, brandy, gin, and other distilled spirits, including all dilutions and mixtures thereof, for non-industrial use"); *id*. at § (a)(6) (defining "wine" as, *inter alia*, containing 7 percent or more alcohol by volume); *id*. at § 211(a)(7) (defining "malt beverage" as "a beverage made by the alcoholic fermentation of an infusion or decoction, or combination of both, in potable brewing water, of malted barley with hops, or their parts, or their products, and with or without other malted cereals, and with or without the addition of unmalted or prepared cereals, other carbohydrates or products prepared therefrom, and with or without the addition of carbon dioxide, and with or without other wholesome products suitable for human food consumption").

The FDA has also noted "that certain curative, therapeutic, or disease-prevention claims for an alcoholic beverage might place the product in the category of a drug under the Federal

Food, Drug, and Cosmetic Act (FFDC Act), 21 U.S.C. 321(g)(1)(B). *See* 68 Fed. Reg. 10076, 10078 (Mar. 3, 2003). The TTB agreed with the FDA, but also acknowledged that the TTB's system of "health claims" regulation is a separate regulatory model that mirrors the FDA's health claim model for foods and dietary supplements. In the preamble to its final rule for health claims and other health-related statements, the TTB explained:

> After giving careful consideration to these comments, and consulting with FDA, TTB does not agree that its health claim regulations should be identical to those of FDA. FDA regulations were promulgated pursuant to a very specific grant of authority by Congress under the NLEA. Because of the differences in statutory authority, as well as the differences in the products regulated under these two statutes, TTB's regulatory scheme for health claim labeling will differ from FDA's regulatory scheme.
>
> However, TTB agrees with the FDA comment in several respects. Most importantly, we agree that it is important to ensure that alcohol beverage producers do not violate the new drug provisions of the FFDC Act when seeking to use specific health claims on alcohol beverage labels. It would be where the use of that claim would render the product subject to FDA's jurisdiction over drugs. Furthermore, FDA's authority over new drugs has significant public health and safety consequences. TTB does not wish to create any confusion on the part of industry members regarding their obligations to comply with FDA's requirements over drug claims.
>
> In the past, ATF merely advised industry members that they should be aware of the fact that the use of a health claim on an alcohol beverage label may subject the product to FDA's jurisdiction. However, after reviewing the comments on this issue, we met with FDA to discuss a process whereby TTB and FDA could consult on the use of specific health claims on alcohol beverage labels. In this way, FDA would have an opportunity to object to the use of a specific health claim, based on its jurisdiction over drugs, prior to any TTB action.
>
> Accordingly, the final rule now provides that TTB will consult with FDA, as needed, on the use of specific health claims on labels. If FDA determines that a specific health claim is a drug claim that is not in compliance with the requirements of the FFDC Act, TTB will not approve the use of such statement on a label. There is no similar provision in the advertising regulations, since advertisers are not required to obtain prior approval from TTB. We will of course consult with FDA, as appropriate, if the question arises as to whether an advertisement is in violation of the FFDC Act.

Id. at 10098.

While the TTB has enacted regulations governing the use and dissemination of "specific health claims," and has accepted jurisdiction by "evaluat[ing] such statements on a case-by-case basis…,"[21] the TTB also lacks authority to impose FDA regulatory requirements on spirit products. Neither the FAA Act nor the interpretive case law confers authority on the TTB to look beyond the TTB's enabling regulations in, for instance, 27 C.F.R. § 7.29(e) to determine whether a product claim is permissible under regulations enforced by other sister agencies without jurisdiction.

The ATF (TTB's predecessor) has acknowledged that "there are differences between ATF's statutory mandate to prevent misleading statements on labels and in advertising of alcoholic beverages under the FAA Act, and the more specific authority given to FDA in regulating health claims on food labels pursuant to the NLEA." *See Health Claims in the Labeling and Advertising of Alcoholic Beverages*, ATF IC 9308, 1993 WL 719948 (ATF Aug. 2, 1993).

Those points notwithstanding, the TTB health claim regulations are clearly designed to exempt certain "health claims" from the federal "drug" model when used for spirit beverages and subject to TTB preapproval. The TTB regulations unambiguously provide for TTB approval of "health claims" and "specific health claims" that "characterize[] the relationship of the malt beverage, alcohol, or any substance found within the malt beverage, to a disease or health-related condition." *See* 27 CFR § 7.54(e)(ii). That language mirrors the FDA's "health claim" exemptions under the NLEA, wherein the FDA approves claims that also "characterize the relationship between the substance in a food to a disease or health-related condition…" *See, e.g.,*

[21] *See, e.g.,* 27 C.F.R. § 7.54(e).

21 C.F.R. § 101.70(f); 21 U.S.C. § 343(r)(1)(B) (defining a health claim to mean a claim that "characterizes the relationship of any nutrient . . . to a disease or a health-related condition . . .").. Through the passage of 27 C.F.R. §§ 7.29, 7.54, and similar regulations, the TTB unambiguously established a pathway for health claim approval that is specific to TTB's jurisdiction and independent of the FDA's statutory authority and regulatory models.

Nonetheless, the health claims requested by this petition are not treatment or drug claims but, rather, claims that describe the role of the NTX® dietary ingredients that is intended to affect the structure or function of humans through well-documented mechanisms showing that NTX® maintains, protects, or supports those structure (to wit, hepatic systems and DNA). The FDA expressly excludes such claims from the definition of "drug" under Section 403(r)(6) of the federal Food, Drug, and Cosmetic Act. *See* 21 U.S.C. § 343(r)(6). Certain of the claims pertain to the reduction in the risk of disease effected by NTX® but they are, in that respect, indistinguishable from claims FDA and the federal courts regard as health claims. The FDA expressly excludes such "health claims" from the definition of "drug." *See id*. at § 343(r)(1)(B), (3)-(5). Although the FDA's regulatory model regarding health claims is not applicable here in the TTB context, the FDA's system—from which the TTB's regulation is apparently modeled—expressly excludes health claims from the "drug" context. *See id*. at § 343(r)(1)(B) (defining health claim as one that characterizes a relationship between a substance and a disease or health-related condition).

H. The Proposed Health-Related Statements Constitute Protected Commercial Speech under *Central Hudson* and Its Progeny

The proposed health-related statements are protected commercial speech under *Central Hudson* and its progeny. *See generally Central Hudson Gas & Elec. Corp. v. Pub. Serv.*

Comm'n of N.Y., 447 U.S. 557 (1980); *see also Rubin v. Coors Brewing Co.*, 514 U.S. 476 (1995) (applying *Central Hudson*'s test to strike regulations prohibiting beer producers from truthfully disclosing the alcohol content of beers). In *Central Hudson*, the U.S. Supreme Court acknowledged that the First Amendment protects commercial speech from unwarranted government intrusion, albeit less so than other constitutionally guaranteed expression. *See* 447 U.S. at 562. "The protection available for particular commercial expression turns on the nature both of the expression and of the governmental interests served by its regulation." *Id*. at 563. If a commercial "communication is neither misleading nor related to unlawful activity, the government's power is more circumscribed." In that instance, courts evaluate four elements in determining whether government censorship of commercial speech violates the First Amendment: (1) whether the speech concerns lawful activity and is not misleading; (2) whether the government's interest in prohibiting the speech is "substantial;" (3) whether the prohibition at issue "directly advances the governmental interest asserted;" and (4) whether the prohibition is "more extensive than is necessary to serve that interest." *Rubin*, 514 U.S. at 482 (citing *Central Hudson*, 447 U.S. 557 (1980)).

"The party seeking to uphold a restriction on commercial speech carries the burden of justifying it." *Bolger v. Youngs Drug Products Corp.*, 463 U.S. 60, 71, n. 20 (1983). "This burden is not satisfied by mere speculation or conjecture; rather, a governmental body seeking to sustain a restriction on commercial speech must demonstrate that the harms it recites are real and that its restriction will in fact alleviate them to a material degree." *Edenfield v. Fane*, 507 U.S. 761, 771 (1993) (citations omitted). To ban the proposed health-related statements, the TTB must show either that the language is not protected speech or that TTB's interest in government censorship is substantial and the method of censorship advances those interests in a direct and

material way and that there are no obvious, less speech-restrictive alternatives (such as claim qualifications). *Id.* at 767.

i. The Health-Related Statements Concern Lawful Activity and are Not Misleading

As explained in section IV(C), *infra*, and through the supporting evidence attached hereto, the available scientific record substantiates the truthfulness of the proposed health-related statements. The sale of Bellion Vodka and/or other alcoholic beverages containing NTX through the use of truthful and non-misleading health claims constitutes constitutionally protected activity. Moreover, no evidence demonstrates that the proposed health-related statements create a misleading impression concerning the effects on health of alcohol. No evidence suggests that Bellion's health claims would promote an increase in alcohol consumption. Where TTB imposes an outright ban on a claim based on the alleged existence of implied claims, the TTB's decision must be supported by empirical evidence demonstrating that consumers actually understand the label to convey the implied claims and are misled by them.[22] The TTB's regulations acknowledge that claims should be remedied through disclaimers. Here, Bellion's claims are supported by reliable scientific evidence. Thus, at worst, the proposed health-related statements are only potentially misleading. That distinction is critical because potentially misleading speech

[22] Where TTB imposes an outright ban on a health-related statements, the TTB's decision must be supported by empirical evidence demonstrating that consumers actually understand the statement to convey the misleading claims, are misled by those claims, and that the proposed qualifying language would not otherwise remedy that misleadingness. *See Fleminger, Inc. v. U.S. Dep't of Health and Human Servs.*, 854 F. Supp. 2d 192, 216 (D. Conn. 2012) (explaining that, based on established precedent, agencies must have "empirical evidence in connection with the government's outright ban on the proposed health claim"); *see also Whitaker v. Thompson*, 248 F. Supp. 2d 1, 11 (D.D.C. 2002) (citing *Pearson v. Shalala*, 164 F.3d 650, 659–60 (D.C. Cir. 1999) (explaining that a complete ban of a claim would be approved only under narrow circumstances, i.e., when there was almost no qualitative evidence in support of the claim and where the government provided empirical evidence proving that the public would still be deceived even if the claim was qualified by a disclaimer").

is entitled to constitutional protection under the First Amendment and may not be banned outright by this or any other federal agency. *See Pearson v. Shalala*, 164 F.3d 650 (D.C. Cir. 1999) ("*Pearson I*").

To establish that the proposed health-related statements are potentially misleading (as opposed to truthful and non-misleading), the TTB must have factual evidence showing that they are misleading before it may censor them because the TTB—not Bellion—has the burden to justify restrictions on speech. *See Pearson I*, 164 F.3d at 659 (explaining, in part, that the required use of disclaimers is a burden on speech). The TTB cannot declare a statement misleading, and bar that statement outright, by uttering the word "misleading" or resorting to categorical labels. To prove any of the proposed health-related statements is deceptive, the TTB "must offer consumer data or other extrinsic evidence to show that the audience to which the advertisement is directed is in fact misled [or capable of being misled] by the advertisement." *Stokely-Van Camp, Inc. v. Coca-Cola Co.*, 646 F. Supp. 2d 510, 525 (S.D.N.Y. 2009) (citing *Time Warner Cable, Inc. v. DIRECTV, Inc.*, 497 F.3d 144, 158 (2d Cir. 2007)); *see also Scotts Co. v. United Indus. Corp.*, 315 F.3d 264, 273 (4th Cir. 2002) (explaining that if a plaintiff challenges "a claim of implied falsehood, a plaintiff must demonstrate, by extrinsic evidence, that the challenged [advertisements] tend to mislead or confuse consumers"); *Pizza Hut, Inc. v. Papa John's Int'l, Inc.*, 117 F.3d 489, 497 (5th Cir. 2000) ("if the statements at issue are either ambiguous or true but misleading, the plaintiff must present evidence of actual deception") (citations omitted).

The TTB cannot show that any of Bellion's proposed health-related statements is misleading, because the TTB cannot show that (1) the health-related statement misleads consumers into thinking that alcoholic beverages containing NTX® are healthy; or (2) that

consumers will consume more alcoholic beverages than they otherwise would without the health-related statement.

Consumers remain aware that alcohol is unhealthy when consumed in excess or on a regular basis. *See* RESTATEMENT (SECOND) OF TORTS § 402A cmt. j (1965) (exempting alcohol sellers from liability for failing to warn of alcohol dangers, which includes dangers from consumption "in excessive quantit[ies]" and consumption "over a long period of time," because those dangers are "generally known and recognized" by the public). Consumer impact surveys in the mid-1990s concerning health claims on wine products found that participants exposed to those health-related statements did not exhibit a diminished understanding of the risks of drinking. *See Lieberman*, *supra*, 58 Food & Drug L.J. at 515. Moreover, the proposed claim qualification, and indeed any comparable and reasonable qualification—which would be acceptable to Bellion—disabuses consumers of any notion that alcohol consumption is safe or that drinking to excess is advisable.

To the extent that the TTB would view the proposed health-related statements as specific health claims, the qualification or disclaimer proposed herein that will appear as part of them ensures that any potential misleadingness as to the effects on health of alcohol consumption will be dispelled. The proposed disclaimer: (1) is sufficiently detailed and qualified with respect to explaining the categories of individuals to whom the claim applies; (2) adequately discloses the health risks associated with both moderate and heavier levels of alcohol consumption; and (3) outlines the categories of individuals for whom any levels of alcohol consumption may cause health risks.

In sum, there is no basis to conclude that the proposed health-related statements, with the accompanying claim qualification or disclaimer, are potentially misleading or misleading in any respect.

ii. Outright Censorship of the Truthful and Non-Misleading Health-Related Statements Does not Advance any Governmental Interest and Contradicts the TTB's Stated Objectives

Under *Central Hudson*, the government must assert a "substantial interest" in restricting speech. *Coors*, 514 U.S. at 483. Assertion of a substantial interest is not a trifling or insignificant burden on government action. Identifying the asserted interest is critical to an assessment under *Central Hudson*.

The TTB has previously explained that health-related statements must be regulated to prevent alcohol abuse by those consumers who might mistake alcohol for a healthy (or at least less harmful) product. In other words, the TTB has historically argued that it has an interest in prohibiting truthful statements which, by implication, "tend to create a misleading impression" that might encourage consumers to consume more alcohol to their detriment. If the TTB claims a state interest in protecting consumers from truthful information that could lead to abusive behaviors, it should be mindful of the fact that courts have already rejected that approach. *See 44 Liquormart*, 517 U.S. at 503 (explaining that courts express skepticism over government interests that "rest on the offensive assumption that the public will respond 'irrationally' to the truth").

Health-related statements for alcoholic beverages do not materially influence consumer drinking patterns, which undercuts the TTB's theory that protection of consumers from health claims is a significant state interest. *See* Lieberman, *The Power of Positive Drinking: Are Alcoholic Beverage Health Claims Constitutionally Protected?* 58 Food & Drug L.J. 511, 515

(2003). The ATF, the TTB's predecessor, considered this issue in 1998 when wine sellers asked for authority to promote the consumption of wine in moderation given evidence that consumption produced beneficial health effects. *Id.* The ATF commissioned a consumer impact study that found health claims on wine labels did not "induce wine drinkers to alter their drinking pattern, quantitatively or otherwise." *Id.* That study also found that "nothing in the proposed labels appeared to diminish focus group participant perceptions about the risk of drinking." *Id.* In other words, the health-related statements did not sway consumers into suddenly believing that the risks of alcohol consumption had dissipated.

Although the TTB might claim a substantial interest in protecting United States consumers from the ills of alcohol abuse, that interest is legally and factually distinct from a state interest in protecting consumers from truthful labeling content. Protecting consumers from truthful, verifiable, and non-misleading ingredient disclosures is a practice at odds with the TTB's mission and purpose, and lacks a "substantial" undergirding state interest. Perhaps for that reason, all nine Justices on the United States Supreme Court agreed that the ATF's prior label restrictions were unconstitutional in *Coors*, and at least one Justice would have applied "full First Amendment protection" to similar label disclosures involving alcohol content. *See Coors Brewing*, 514 U .S. at 491-92 (Stevens, J., concurring).

iii. Censoring the Health-Related Statements Will Not Advance an Interest in Protecting Consumers from the Ills of Alcohol Abuse

Even if the proposed health-related statements are banned, there is "no evidence to suggest that [the TTB's] speech prohibition will *significantly* reduce [or effect] marketwide consumption." *See 44 Liquormart*, 517 U.S. at 506. Under the third element of *Central Hudson*, a restriction on commercial speech is only valid if it directly advances the asserted governmental interest. *Coors*, 514 U.S. at 486. The government bears the burden "of showing that the

challenged regulation advances the Government's interest 'in a direct and material way.'" *Id.* at 486–87 (quoting *Edenfield v, Fane*, 507 U.S. 761, 767 (1993)). "That burden 'is not satisfied by mere speculation or conjecture; rather, a governmental body seeking to sustain a restriction on commercial speech must demonstrate that the harms it recites are real and that its restriction will in fact alleviate them to a material degree.'" *Id.* at 487 (quoting *Edenfield*, 507 U.S. at 770–71).

To meet its burden and show that regulation advances the governmental interest in a "direct and material way," the TTB must produce actual evidence that allowing the speech would harm the interest it seeks to further through the prevention of that speech. *See Pearson v. Edgar*, 153 F.3d 397, 404 (7th Cir. 1998) (overturning regulation prohibiting real estate brokers from soliciting where government "produced no evidence in this case that real estate solicitation harms or threatens to harm residential privacy"). The courts have made clear the TTB cannot meet that burden "by mere speculation or conjecture; rather a governmental body seeking to sustain a restriction on commercial speech must demonstrate that the harms it recites are real and that its restriction will in fact alleviate them to a material degree." *Fla. Bar v. Went For It, Inc.*, 515 U.S. 618, 625–26 (1995). "Thus, the government must come forward with some quantum of evidence, beyond its own belief in the necessity for regulation, that the harms it seeks to remedy are concrete and that its regulatory regime advances the stated goals." *Pagan v. Fruchey*, 492 F.3d 766, 771 (6th Cir. 2007) (citing *Edenfield*, 507 U.S. at 770–72).

In *Pagan*, for instance, the Sixth Circuit concluded that an affidavit submitted by the government was insufficient to prove that the regulation at issue, the posting of "for sale" signs on cars, directly and materially advanced the state's interests in traffic safety and aesthetics. *Id.* at 772–73. While the government argued that "it would be difficult, expensive, and time-consuming to conduct studies and provide empirical evidence in support of [the regulation]," the

court held that government must nevertheless offer some "actual evidence" that the regulation "will directly advance the government's asserted interest." *Id.* at 773–74; *cf. Anderson v. Treadwell*, 284 F.3d 453, 462 (2d Cir. 2002).

The TTB must have "credible evidence" that allowing the speech at issue would harm the interest asserted. *Id.* at 489; s*ee also 44 Liquormart*, 517 U.S. at 503 (requiring the government to provide evidence that prohibiting price advertising would actually advance the governmental interest in temperance). For example, in *Coors* the government asserted that allowing breweries to disclose the amount of alcohol on their labels would promote "strength wars."[23] *Id.* However, the Court recognized that prohibition of alcohol content on beer labels failed to suppress strength wars to any degree. *Id*. at 490–91 (noting that "the Government did not offer any convincing evidence that the labeling ban has inhibited strength wars").

Here the TTB has no credible evidence that the proposed health-related statements would harm any state interest or that consumers would be misled by them, especially when those health claims are accompanied by the proposed disclaimer. Consumers decide how to drink alcoholic beverages (quantitatively and qualitatively) based on a variety of reasons that may include sociological and psychological factors. Convenience and circumstance likely factor more in the decision than health related-statements. For instance, the quantity of alcohol consumed may depend on the social environment, the availability of transportation, the age of the drinker, etc. Accordingly, the concept that prohibiting a health-related statement will influence the rate, amount, of frequency of alcohol consumption is sheer speculation.

iv. Prohibiting the Proposed Health-Related Statements Is Not Sufficiently Tailored to Any Governmental Goal

[23] A strength war, in that context, is a competition between breweries who "seek to compete for customers on the basis of alcohol content." *Coors*, 514 U.S. at 483.

To pass constitutional muster under *Central Hudson*, the final analysis requires the TTB to prove that a speech restriction is sufficiently tailored to its articulated goal. *Coors,* 514 U.S. at 490. Assuming *arguendo* that the TTB has a defined and substantial interest in regulating the proposed health-related statements, that interest is not directly advanced by the TTB's censorship of the claims here in isssue.

Even assuming that the TTB could demonstrate an important state interest, and that unqualified health-related statement have the potential to mislead, the TTB must then *prove* that there are no less speech-restrictive alternatives, such as the disclaimers required under its own regulations for specific health claims. *Pearson I,* 164 F.3d at 658-59 (requiring reliance on disclaimers as a less speech restrictive alternative to outright suppression); *Alliance for Natural Health U.S. v. Sebelius*, 714 F. Supp. 2d 48, 71 (D.D.C. 2010) ("*ANH I*") (invalidating FDA disclaimer language and holding that FDA acted unconstitutionally by requiring a more onerous disclaimer without considering whether a short and succinct disclaimer would be a less restrictive means); *see also Pearson v. Shalala*, 130 F. Supp. 2d 105, 120 (D.D.C. 2001) ("*Pearson II*").

Here, as discussed above, the Petitioners propose a disclaimer to accompany the health-related statements that is sufficient to cure any potential for misleadingness regarding the effects of alcohol on health. The Petitioners proposed that disclaimer despite TTB having conceded in prior agency statements that burdensome disclaimers for specific health claims would be "extremely unlikely [to] fit on a normal alcoholic beverage label." *See* Health Claims in the Labeling and Advertising of Alcoholic Beverages, ATF IC 93-8, 1993 WL 719948 (ATF Aug. 2, 1993). Because "no label has [ever] met," the standard clearly reveals that the burdens of the TTB regulations have, to this point, effected a de facto market ban. *See, e.g.*, Erik Bierbauer,

Liquid Honesty: The First Amendment right to Market the Health Benefits of Moderate Alcohol Consumption, 74 N.Y.U. L. Rev. 1057, 1068 (1999) (explaining that "[t]he only health statement that ATF said it would accept was a four-page report with thirty-four footnotes, which the agency said presented a balanced view of drinking's good and ill effects.").

To the extent that the TTB will require a more onerous, lengthy, and burdensome disclaimer than the one proposed, the TTB would violate the First Amendment's requirement for reasonable claim qualification, which is to mandate "short, succinct, and accurate" qualifications. *Pearson II*, 130 F. Supp. 2d at 120. Moreover, there is no proof that onerous and lengthy disclaimers are the only ones capable of effectuating a legitimate government interest such that there are no "less restrictive means" through short, succinct and accurate disclaimers, such as the one proposed in this petition. *See Pearson I*, 164 F.3d at 658. Absent extrinsic evidence that such onerous disclaimers are required to cure any alleged misleadingness caused by the proposed health-related statements, requiring onerous disclaimers is unconstitutional. Indeed, the federal courts have explained repeatedly that the government acts unconstitutionally unless it can "demonstrate with empirical evidence that [much shorter] disclaimers … would bewilder consumers and fail to correct for deceptiveness." *Whitaker v. Thompson*, 248 F. Supp. 2d 1, 5 (D.D.C. 2002); *Pearson I*, 164 F.3d at 659-60; *ANH I*, 714 F. Supp. 2d at 63 (invalidating FDA censorship because the "[a]gency has not provided any empirical evidence, such as 'studies' or 'anecdotal evidence,' that consumers would be misled").

V. Conclusion

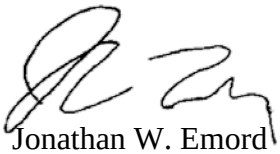
For the foregoing reasons, the Petitioners request that TTB authorize the proposed health-related statements concerning NTX®. Those claims include the following health claims in Bellion labels, labeling, advertising, and promotional statements:

- NTX® provides antioxidant and anti-inflammatory support;
- NTX® helps protect against alcohol-induced oxidative damage to the liver;
- NTX® helps maintain normal liver enzyme production and function;
- NTX® supports normal liver defenses and regenerative mechanisms;
- NTX® reduces the risk of alcohol-induced liver diseases, including fibrosis and cirrhosis;
- NTX® helps maintain normal liver functions;
- NTX® helps protect DNA from alcohol-induced damage; and
- NTX® reduces alcohol-induced DNA damage

Any questions concerning this Petition may be directed to Jonathan W. Emord, Esq. Emord & Associates, P.C., 11808 Wolf Run Lane, Clifton, VA 20124, (202) 466-6937. The undersigned certify on behalf of the Petitioners that to the best of their knowledge and belief, the Petition includes all information and views on which the Petitioners rely and is a representative and balanced submission that includes unfavorable information as well as favorable information known by the Petitioner to be pertinent to evaluation of the proposed health claims.

DATED: April 12, 2016.

Sincerely,



Jonathan W. Emord

Re: Petition for Health Related Statements for Bellion Vodka with NTX®

Dear Mr. Manfreda and Mss. Knapp and Davis:

Please find enclosed two hardcopies of Bellion Sprits, L.L.C.'s and Chigurupati Technologies Private Ltd.'s petition for health-related statements concerning the effect of NTX® in distilled spirits and/or other alcoholic beverages. We have enclosed compact discs containing electronic versions of the petitions in PDF Format. Those CDs contain two versions of Exhibit 5: a public redacted version and a confidential version containing confidential and proprietary data subject to protection under 5 U.S.C. § 552(b)(4).

Please do not hesitate to contact us if you have any questions.

Sincerely,

Jonathan W. Emord
Peter A. Arhangelsky

RESEARCH SUPPORTING THE HEALTH CLAIMS FOR NTX, A PRODUCT COMPOSED OF GLYCYRRHIZIN AND MANNITOL, IN CONJUNCTION WITH ALCOHOL CONSUMPTION

SIDNEY J. STOHS, Ph.D., FACN, CNS, ATS, FAPhA

Dean Emeritus, Creighton University Medical Center

ABSTRACT

The detrimental effects of chronic and heavy alcohol consumption are well documented, and alcohol is a risk factor or cause of numerous diseases. The most common problem associated with chronic alcohol consumption is alcoholic liver disease which can range from hepatic steatosis to more advanced stages as hepatitis, cirrhosis, hepatocellular carcinoma and ultimately liver failure. NTX is a patented product composed of the primary ingredients glycyrrhizin and mannitol that act synergistically. Numerous studies in humans and animals have demonstrated the liver protective effects of NTX as well as its individual components during alcohol consumption. Furthermore, the safety of the ingredients in NTX is well-established. Therefore, health claims regarding NTX have been set forth based on the totality of the scientific literature, and each health claim is substantiated and supported by the scientific literature.

INTRODUCTION

The detrimental effects of chronic and/or heavy alcohol consumption are well established, and alcohol is considered a risk factor or cause of numerous diseases. More than 50 % of Americans consume alcohol. According to a 2014 report of the Center for Disease Control (CDC), the cost for excessive drinking in the United

States was $223.5 billion in 2006 in terms of health care costs and lost productivity[1], a number that undoubtedly has increased in subsequent years. Furthermore, the CDC estimates that there are approximately 88,000 alcohol related deaths annually[2].

The most common problem associated with chronic alcohol consumption is alcoholic liver disease which is defined by histological lesions on the liver that range from hepatic steatosis to more advanced stages as alcoholic steatohepatitis, cirrhosis, hepatocellular carcinoma and liver failure due to necrosis or apoptosis (programmed cell death)[3,4]. Over 14,000 deaths occur annually in the United States due to alcoholic liver cirrhosis[4].

The mechanisms associated with alcohol toxicity and the induction of alcoholic liver disease can be summarized as follows: metabolism of alcohol to highly toxic acetaldehyde and free radical species, production of reactive oxygen (ROS) and nitrogen species with resulting oxidative stress, release of inflammatory cytokines as tumor necrosis factor-alpha (TNF-α) and interleukin-6 (IL-6), abnormal lipid metabolism, oxidative DNA damage, formation of protein and DNA adducts with metabolites of alcohol and acetaldehyde, and ultimately induction of apoptosis or necrosis with subsequent multi-system organ failure[3-9].

Biomarkers are biological indicators of the state of health of an organ or tissue. Just as blood sugar (glucose) elevation is indicative of and associated with diabetes, various common biomarkers are useful in assessing the existence, progression and pathogenesis of alcoholic liver disease. These biomarkers include measurements of the blood serum levels of the enzymes alanine aminotransferase (ALT), aspartate aminotransferase (AST), gamma-glutamyltransferase (GGT) and alkaline phosphatase (ALP). Elevations of the serum levels of these enzymes occur when the liver is damaged as is the case with alcoholic liver disease. Conversely, decreases in the serum levels of these enzymes occur as the liver begins to heal[8-12].

Other biomarkers that are commonly used to assess the stages of alcoholic liver disease include total bilirubin, lipid profiles (cholesterol and triglycerides), hemoglobin or serum ferritin, albumin, platelets, prothrombin time and

international normalized ratio (INR). For example, elevations in blood levels of cholesterol and triglycerides are associated with faulty liver metabolism of these lipids which occurs in conjunction with alcoholic liver disease. Similarly, elevated bilirubin occurs as a result of faulty liver metabolism.

As previously noted, the hepatic metabolism of alcohol results in the production of free radicals and reactive oxygen species (ROS) leading to oxidative stress which produces tissue damaging effects. Markers of oxidative stress and oxidative tissue damage include reactive oxygen species (ROS) production, the lipid metabolite malondialdehyde (MDA), protein carbonyl formation, and DNA damage. Increases in these biomarkers serve as indices and measures of alcoholic liver damage. Reduced glutathione (GSH) content is one of the primary intracellular antioxidants and chemoprotectants in human tissues, and a decrease in GSH content occurs as it neutralizes ROS and free radicals. Therefore, a decrease in GSH is associated with an increase in oxidative stress as occurs in the case of alcoholic liver disease[8-12].

Blood and tissue levels of the enzymes catalase, glutathione peroxidase (GPX) and superoxide peroxidase (SOD) are also used to obtain information regarding alcoholic liver disease[10-12]. These enzymes play important roles in the decomposition of ROS as hydrogen peroxide. Increases in the levels of these enzymes are indicative of hepatoprotection.

In individuals with alcohol-associated steatosis, studies indicate that approximately 20% will develop cirrhosis within 10 years[6], and it is estimated that 20% of heavy drinkers will develop acute alcoholic hepatitis[13]. The two primary approaches for successful prevention and reversal of liver damage are abstinence from alcohol and appropriate nutritional support. Realistically, one cannot expect the vast majority of alcohol consumers to abstain. Therefore, there is a pressing need to develop safer strategies for alcohol consumption and treatment in order to reduce alcohol-associated morbidity and mortality, and the high cost to society.

The high morbidity and mortality rate of alcoholic liver disease is attributed to the cascading sequence of events described above which can ultimately culminate in multisystem organ failure and death[3-9,13]. Systems designed to prevent and treat alcohol-induced liver toxicity and alcoholic liver disease must therefore focus on disrupting, inhibiting and/or reversing these pathological pathways. As a consequence, a new category of alcoholic beverages called Functional Spirits has been created and a product has been patented[14] that prevents and/or ameliorates the hepatotoxic effects of alcohol while retaining it desired characteristics.

NTX is a patented product composed of the primary ingredients glycyrrhizin glycyrrhizic acid) and mannitol[14]. It also contains potassium sorbate as an antioxidant, preservative and antimicrobial. The potassium may also provide benefits with respect to electrolyte balance. Recent studies in humans and animals have demonstrated the hepato-protective effects of NTX during alcohol consumption[14-19].

In a randomized, double-blind, placebo-controlled cross-over clinical trial involving human 12 subjects, NTX afforded significant liver protection during 12 days of alcohol consumption as evidenced by significant decreases in the serum levels of the enzyme biomarkers of liver toxicity ALT, AST, GGT and ALP[15]. No adverse effects were observed by any of the subjects in the presence or absence of the NTX.

A second randomized, double-blind, placebo-controlled cross-over clinical trial involving human 31 subjects was conducted whereby all participants received 1.5 g alcohol/kg with and without NTX. A seven day washout was provided between treatments[16]. Consumption of alcohol alone caused an increase in serum ROS and ROS metabolites which persisted for up to 4 hours. In addition, alcohol consumption resulted in a decrease in serum GSH, an increase in MDA (lipid peroxidation), an increase in protein carbonyl, and an increase in oxidative DNA damage in peripheral lymphocytes as determined by the single cell electrophoresis comet assay, the cytokinesis-block micronucleus assay, and 8-

hydroxy-2-deoxyguanosine formation. Consumption of alcohol with NTX significantly reduced the levels of ROS and all the oxidative markers. According to the authors, the results indicated that NTX may "be effective in reducing alcohol-induced pathophysiological changes"[16].

A double blind, comparative, cross-over clinical trial was conducted which examined the effects of alcohol on blood levels of ROS in the absence and presence of co-administered NTX[17]. Twelve normal healthy subjects were used. The results demonstrated that NTX significantly dampened the alcohol-induced generation of ROS and ROS metabolites. NTX also decreased serum MDA, a product of alcohol-induced lipid peroxidation, while increasing serum levels of the endogenous antioxidant and chemoprotectant GSH. Furthermore, NTX administration with alcohol significantly decreased serum protein carbonyl levels which are another marker of alcohol-induced oxidative stress[17].

A 28 day experiment was conducted in rats that daily received 2.5 g/kg/day with or without various doses of mannitol, glycyrrhizin or both[14]. The results demonstrated that mannitol and glycyrrhizin alone afforded significant hepato-protection while the combination of these two substances (NTX) was synergistic, affording protection that was greater than the sum of the individual ingredients. The combination restored biomarkers of liver function to as much as 80 % of normal. The combination of mannitol and glycyrrhizin (NTX) provided significant hepato-protection from alcohol toxicity as evidenced by decreases in serum ALT levels, decreases in the levels of the inflammatory cytokine TNF-α, and decreases in the lipid peroxidation product MDA.

This combination (NTX) product synergistically decreased alcohol induced production of reactive oxygen species (ROS) by enhancing the levels of the enzymes catalase, GPX and SOD that decompose tissue damaging ROS[14]. Reduced glutathione (GSH) is the primary antioxidant within cells that protects against ROS. Alcohol consumption results in a depletion of GSH due to alcohol-induced production of ROS. Concurrent consumption of the combination of mannitol and

glycyrrhizin (NTX) provided significant restoration of endogenous GSH levels in the liver[14], indicative of a more normal healthy functioning liver.

A study was conducted in rats that evaluated the effects of NTX on oxidative stress induced by a single dose of alcohol[18]. The alcohol alone resulted in an increase in the production of ROS, a decrease in GSH and an increase in MDA, all indicators of alcohol-induced toxicity. Co-administration of NTX with the alcohol resulted in a significant modulation of these alcohol-induced effects, indicating a hepato-protective effect of the NTX.

Another study in rats has evaluated the hepatoprotective effects of NTX against alcohol induced hepatotoxicity[19]. Rats were given orally 1, 2 or 3 grams of ethanol per kg daily for 28 days with and without NTX. Alcohol treatment caused the elevation of serum enzymes ALT, AST, GGT and ALP, denoting hepatic toxicity. In addition, the lipid peroxidation product MDA was elevated while the endogenous antioxidant GSH was decreased. Co-administration of NTX with the alcohol resulted in 20-40 % decreases in the levels of ALT, AST, GGT and ALP, demonstrating the hepatoprotective effects of the NTX. Furthermore, 26-47 % decreases occurred in lipid peroxidation (MDA) with 24-28 % increases in the intracellular antioxidant and hepatoprotectant GSH.

The published scientific literature has been reviewed regarding glycyrrhizin and mannitol as well as potassium sorbate. The author used PubMed as well as Google Scholar. PubMed is the search engine which accesses primarily the MEDLINE database of references and abstracts on biomedical topics and life sciences. The PubMed database is maintained by the U.S. National Library of Medicine at the National Institutes of Health. Google Scholar also covers articles in journals that are less well known as well as a greater number of foreign language journals than PubMed. As a consequence, the author located a number of articles via Google Scholar that were not detected by PubMed.

This review addresses not only human studies associated with alcoholic liver disease, NTX and its components glycyrrhizin and mannitol, but also relevant

animal and in vitro studies. Animal and in vitro studies provide valuable information regarding mechanisms of action, safety and efficacy that can be readily extrapolated to humans, and that cannot be conducted in humans because of ethical and potential safety considerations. Furthermore, animal studies corroborate and can greatly extend information derived from human studies.

In summary, the above human and animal studies demonstrate that co-consumption of NTX with alcohol can ameliorate the hepatotoxic effects of alcohol and thereby improve the health of alcohol consumers as well as decrease the alcohol-related burden on society in a cost-effective manner.

HEALTH CLAIMS

Animal and human studies have been conducted with NTX in combination with alcohol[14-19], and described above. In addition, over 70 human, animal and in vitro studies have been conducted and published on the hepatoprotective, antioxidant and anti-inflammatory effects of glycyrrhizin and mannitol, the key components of NTX which have been shown to work synergisitcally[14]. Therefore, the following health claims regarding NTX have been set forth. Each health claim is substantiated and supported by the available scientific literature.

- **Provides antioxidant and anti-inflammatory support**
- **Helps protect against oxidative damage to the liver**
- **Helps maintain normal liver enzyme production and function**
- **Supports normal liver defenses and regenerative mechanisms**
- **Reduces the risk of liver diseases including fibrosis and cirrhosis**
- **Ameliorates the symptoms associated with liver disease including fibrosis and cirrhosis**
- **Helps maintain normal liver functions**
- **Helps protect DNA from alcohol-induced damage**
- **Reduces alcohol-induced DNA damage**

PROVIDES ANTIOXIDANT AND ANTI-INFLAMMATORY SUPPORT

Human and animal studies have shown that NTX decreases alcohol-induced production of reactive oxygen species (ROS) and ROS metabolites, lipid peroxidation (MDA formation) and carbonyl protein formation, while increasing the levels of the endogenous antioxidant reduced glutathione (GSH)[14, 16-19]. Furthermore, NTX decreases the alcohol-induced increase in DNA damage in human peripheral lymphocytes as determined by the single cell electrophoresis comet assay, the cytokinesis-block micronucleus assay, and 8-hydroxy-2-deoxyguanosine formation[16]. NTX also enhances the levels of the enzymes catalase, GPX and SOD that decompose ROS[14], thereby affording protection from the tissue damaging effects of ROS.

In an animal study, a licorice extract predominantly containing glycyrrhizin has been shown to effectively inhibit alcohol induced increases in TNF-α, lipid accumulation in liver (steatosis) and decreases in the antioxidant GSH[20]. The hepatoprotective effect was confirmed histologically. In animals, glycyrrhizin also inhibits alcohol-induced increases in the inflammatory cytokine NF-κB[21, 22], and increases in MDA as well as serum lipids[23], while preventing liver injury and cirrhosis.

Various in vitro studies have demonstrated the antioxidant and free radical scavenging ability of glycyrrhizin[24-29]. In cell culture experiments, glycyrrhizin has been shown to inhibit inflammatory TNF-α secretion[30,31] and MDA production (lipid peroxidation)[32-34], while enhancing the antioxidant enzyme SOD and the antioxidant and tissue protectant GSH[32,33,35].

In a number of animal experiments, glycyrrhizin has been shown to decrease the production of the inflammatory cytokines TNF-α, IL-1 and IL-6[27, 36-38], decrease lipid peroxidation (MDA)[36, 38-40], increase hepatic GSH content[40,41], and increase levels of the reactive species-eliminating enzymes SOD and GPx[42].

Glycyrrhizin also provides protection against nephrotoxic drugs[43] as well as experimental acute pancreatitis in rats[44]. In the latter case, glycyrrhizin decreased

concentrations of the inflammatory cytokines TNF-α, IL-1 and IL-6 and also decreased MDA production. In this study, the protective effects of glycyrrhizin were corroborated histologically[44].

Glycyrrhizin has been shown to ameliorate liver damage associated with high fructose intake in rats[38] which is characterized by oxidative tissue damage and inflammation. Glycyrrhizin administration significantly deceased levels of AST, ALT, ALP, ROS, carbonyl protein, TNF-α, lipid peroxidation (MDA) and apoptosis, all characteristic of liver damage. The antioxidant, anti-inflammatory and hepatoprotective effects of the glycyrrhizin were affirmed histologically[38].

Mannitol is the second of the two primary components of NTX. Several human studies have demonstrated the antioxidant and tissue protective effects of mannitol. Mannitol has been shown to exhibit tissue protective effects in acute ischemic-reperfusion injuries[45], and antioxidant and free radical scavenging properties in conjunction with cardiopulmonary bypass[46]. Mannitol is used as an anti-inflammatory and antioxidant in tissue baths associated with kidney transplants[47].

In a study in rats, mannitol was demonstrated to provide protection against alcohol-induced gastric mucosal damage due to its antioxidant and anti-inflammatory properties[48]. Mannitol has also been shown to exhibit anti-inflammatory and antioxidant activity in rats after traumatic brain injury[49]. Mannitol decreased production of MDA and normalized the levels of the antioxidant enzymes catalase and GPx.

In summary, over 30 human, animal and in vitro published studies have confirmed the antioxidant and anti-inflammatory properties of NTX and its primary components glycyrrhizin and mannitol. It should be noted that glycyrrhizin and mannitol afford tissue and organ protection against oxidative stress and ROS regardless of their source, including chronic alcohol consumption.

HELPS PROTECT AGAINST OXIDATIVE DAMAGE TO THE LIVER

As noted above, common biomarkers used in assessing the existence and progression of alcoholic liver damage and disease include the measurement of serum levels of the enzymes alanine aminotransferase (ALT), aspartate aminotransferase (AST), gamma-glutamyltransferase (GGT) and alkaline phosphatase (ALP)[50-52]. Other biomarkers that are also commonly used to determine the degree of tissue damage include total bilirubin, lipid profiles, hemoglobin or serum ferritin, albumin, and platelets.

A randomized, double-blind, placebo-controlled clinical trials involving 12 human subjects in each study have shown that NTX provides significant liver protection during 12 days of alcohol consumption as evidenced by decreases in the biomarkers of liver toxicity ALT, AST, GGT and ALP[15].

A second randomized, double-blind, placebo-controlled cross-over clinical trial involving human 31 subjects was conducted whereby all participants received alcohol with and without NTX. A seven day cross-over washout was provided between treatments[16]. Consumption of alcohol alone caused an increase in serum ROS and ROS metabolites, a decrease in serum GSH, an increase in MDA, an increase in protein carbonyl, and an increase in DNA damage in peripheral lymphocytes as determined by the single cell electrophoresis comet assay, the cytokinesis-block micronucleus assay, and 8-hydroxy-2-deoxyguanosine formation. Co-consumption of alcohol with NTX significantly reduced the levels of ROS and all the oxidative markers, thus demonstrating the tissue protective effects of NTX.

A meta-analysis of 12 randomized controlled trials (RCTs) has been published that summarizes the effects of a glycyrrhizin product on liver function in 838 patients with alcoholic liver disease[53]. The study results showed that glycyrrhizin significantly decreased serum ALT and AST levels and the authors concluded that the glycyrrhizin product significantly improved liver function in alcoholic liver disease[53].

Several animal studies have demonstrated that NTX provides significant protection against alcohol-induced oxidative damage to the liver as evidenced by decreases in serum levels of ALT, AST, GGT and ALP[14,19]. Increases in hepatic MDA are an indicator of oxidative liver damage, and NTX significantly reduced the alcohol-induced production of MDA[14,19]. The hepatoprotective effects of NTX in rats were confirmed by histopathological examination of livers that revealed a marked reduction in alcohol-induced lesions with an absence of necrotic cells[19]

In a number of animal experiments, glycyrrhizin has been shown to decrease the production of MDA (lipid peroxidation)[36, 38-40], increase hepatic content of the antioxidant and free radical scavenger GSH[40,41], and increase levels of the reactive species-eliminating enzymes SOD and GPx[42]. Glycyrrhizin also provides protection against nephrotoxic drugs[43] as well as experimental acute pancreatitis in rats[44]. In the latter case, glycyrrhizin decreased MDA production, am indicator of liver oxidative damage, and the protective effects of glycyrrhizin were demonstrated histologically[44].

Glycyrrhizin has been shown to ameliorate oxidative liver damage associated with high fructose intake in rats[38]. Glycyrrhizin administration significantly deceased levels of AST, ALT, ALP, ROS, carbonyl protein, TNF-α, lipid peroxidation (MDA) and apoptosis, all characteristic of oxidative liver damage. The antioxidant and hepatoprotective effects of the glycyrrhizin were affirmed histologically[38].

In cell cultures, glycyrrhizin has been shown to inhibit TNF-α secretion[30,31] and MDA production[32-34], while enhancing the antioxidant enzyme SOD and the endogenous antioxidant GSH[32,33,35].

Glycyrrhizin, one of the active constituents in NTX, has been shown to significantly reduce serum ALT and AST in patients with chronic hepatitis[54-67], with the reduction in these enzymes being an indication of the extent of liver damage. The frequency of ALT normalization was dependent upon duration of glycyrrhizin administration, with the highest normalization reported being approximately 35 %[54]. The improved health of the liver was confirmed histologically in one study where glycyrrhizin treatment resulted in a 45 % improvement in the necrosis

score[63]. Glycyrrhizin administration has also been shown to decrease the incidence of hepatocarcinoma in individuals with hepatitis by as much as 25 %[54, 59, 65-67].

A meta-analysis of 9 randomized controlled trials involving 687 patients with chronic hepatitis treated with diammonium glycyrrhizinate, a salt of glycyrrhizin, has been published[68]. The study concluded that the diammonium glycyrrhizinate significantly decreased serum ALT and AST levels as well as provided significant improvements in total bilirubin and albumin, thus demonstrating improved liver function.

Another meta-analysis reviewed 24 randomized control trials involving 3201 patients with chronic hepatitis who were treated with diammonium glycyrrhizinate[69]. The authors concluded that the diammonium glycyrrhizinate significantly reduced serum ALT and total bilirubin and ameliorated fibrosis.

In summary, approximately 50 published human studies as well as a number of animal studies have shown that NTX as well as its primary active constituents glycyrrhizin and mannitol afford protection against oxidative damage to the liver, keeping in mind that the mechanism of alcohol toxicity and liver disease involves oxidative stress and oxidative damage.

HELPS MAINTAIN NORMAL LIVER ENZYME PRODUCTION AND FUNCTION

Animal and cell culture studies have shown that NTX and its active constituents glycyrrhizin and mannitol help maintain a wide range of liver enzymes at normal levels including ALT, AST, GGT and ALP, affirming the lack of alcohol-induced inflammation and tissue damage. Furthermore, antioxidant enzymes as SOD, GPX and catalase are supported so that they can preclude formation of products of oxidative tissue damage including ROS, carbonyl protein and MDA. These results demonstrate that glycyrrhizin and mannitol protect the liver, and support and facilitate normal liver function.

A randomized, double-blind, placebo-controlled clinical trial involving 12 human subjects received alcohol daily for 12 days with or without NTX. NTX co-administration with alcohol provided significant decreases and normalization in the enzyme biomarkers of liver toxicity ALT, AST, GGT and ALP[15,16]. The results demonstrated that NTX precluded alcohol toxicity and helped maintain normal liver function.

A second randomized, double-blind, placebo-controlled cross-over clinical trial involving human 31 subjects was conducted whereby all participants received a single dose of alcohol with and without NTX. A seven day washout was provided between treatments[16]. Consumption of alcohol alone caused an increase in serum ROS and ROS metabolites, a decrease in serum GSH, an increase in MDA, an increase in protein carbonyl, and an increase in DNA damage in peripheral lymphocytes as determined by the single cell electrophoresis comet assay, the cytokinesis-block micronucleus assay, and 8-hydroxy-2-deoxyguanosine formation. Co-consumption of alcohol with NTX significantly reduced the levels of ROS and all the oxidative markers[16], thus helping to maintain normal liver enzyme levels and functions.

Glycyrrhizin, one of the active constituents in NTX, has been shown in a number of clinical studies to significantly reduce and normalize serum ALT and AST in patients with chronic hepatitis[54-67]. The frequency of ALT normalization was dependent upon duration of glycyrrhizin administration, with the highest normalization reported being approximately 35 %[54].

Several animal studies have demonstrated that NTX provides significant protection against alcohol-induced oxidative damage to the liver as evidenced by decreases and normalization of the serum levels of ALT, AST, GGT and ALP[14,19]. Rats were given ethanol daily for 28 days with and without NTX[19]. Alcohol treatment produced an elevation of serum enzymes ALT, AST, GGT and ALP, denoting hepatic toxicity. In addition, the endogenous antioxidant GSH was decreased. Co-administration of NTX with the alcohol resulted in 20-40 %

decreases in the levels of ALT, AST, GGT and ALP with significant increases in the antioxidant GSH, demonstrating the ability of NTX to decrease the hepatotoxic effects of alcohol, and help maintain normal liver enzyme levels. The ability of NTX to provide protection against alcohol-induced toxicity was confirmed by histopathological examination of the livers[19].

The combination of glycyrrhizin and mannitol, the active ingredients in NTX, synergistically decreased alcohol induced production of reactive oxygen species (ROS) by enhancing the levels of the enzymes catalase, GPX and SOD that decompose tissue damaging ROS[14], thus contributing to the maintenance of normal liver function. In addition, consumption of mannitol and glycyrrhizin (NTX) prevented alcohol-induced depletion of endogenous GSH levels in the liver[14], indicative of hepatoprotection by NTX and a normal healthy functioning liver.

Glycyrrhizin ameliorates oxidative liver damage associated with high fructose intake in rats[38]. Glycyrrhizin administration significantly normalized levels of AST, ALT, ALP, ROS, carbonyl protein, lipid peroxidation (MDA) and apoptosis, all characteristic of oxidative liver damage. The tissue effects of the glycyrrhizin and normalization of liver function were affirmed histologically[38].

In cell culture experiments, glycyrrhizin has been shown to inhibit TNF-α secretion[30,31] and MDA production[32-34], while enhancing the antioxidant enzyme SOD and the antioxidant GSH[32,33,35].

In summary, numerous published human, animal and cell culture studies have shown that NTX and its primary active constituents glycyrrhizin and mannitol normalize a wide range of liver enzymes including ALT, AST, GGT, ALP, SOD, GPX and catalase while inhibiting alcohol-induced inflammation and formation of products of oxidative tissue damage including ROS, carbonyl protein and MDA. These results demonstrate that glycyrrhizin and mannitol protect the liver, and support and facilitate normal liver function.

SUPPORTS NORMAL LIVER DEFENSES AND REGENERATIVE MECHANISMS

Almost 50 published human clinical studies and a wide variety on animal studies have demonstrated that NTX and its individual components glycyrrhizin and mannitol support normal defense mechanisms against alcohol and other hepatotoxins, allowing normal function and regeneration of the liver.

A randomized, double-blind, placebo-controlled cross-over clinical trial has demonstrated that NTX provides significant liver protection during 12 days of alcohol consumption as compared to receiving alcohol alone as evidenced by decreases and normalization of the hepatic enzyme biomarkers of liver toxicity ALT, AST, GGT and ALP[15]. A four week washout period was provided between the cross-over treatments.

A second randomized, double-blind, placebo-controlled cross-over clinical trial involving human 31 subjects was conducted whereby all participants received a single dose alcohol with and without NTX. A seven day washout was provided between treatments[16]. Consumption of alcohol alone caused an increase in serum ROS and ROS metabolites, a decrease in serum GSH, an increase in MDA, an increase in protein carbonyl, and an increase in DNA damage in peripheral lymphocytes as determined by the single cell electrophoresis comet assay, the cytokinesis-block micronucleus assay, and 8-hydroxy-2-deoxyguanosine formation. Consumption of alcohol with NTX significantly reduced the levels of ROS and all the oxidative markers and increased serum GSH. The results indicated that NTX may "be effective in reducing alcohol-induced pathophysiological changes"[16].

A double blind, comparative, cross-over clinical trial was conducted which examined the effects of alcohol on blood levels of ROS in the absence and presence of co-administered NTX[17]. The results demonstrated that NTX significantly decreased the alcohol-induced generation of ROS and ROS metabolites, and decreased serum lipid peroxidation product MDA, while increasing serum levels of the endogenous antioxidant GSH. NTX administration

with alcohol also significantly decreased serum protein carbonyl levels which are another marker of alcohol-induced oxidative stress[17]. Thus, NTX co-administration with alcohol decreased oxidative tissue damage and supported normal liver function.

A 28 day experiment was conducted in rats that daily received alcohol with or without various doses of mannitol, glycyrrhizin or both[14]. The results demonstrated that individually mannitol and glycyrrhizin provided significant hepato-protection while the combination of these two substances (NTX) was synergistic, affording protection that was greater than the sum of the individual ingredients. The combination of glycyrrhizin and mannitol restored biomarkers of liver function to as much as 80 % of normal. The combination (NTX) also provided significant hepatoprotection from alcohol toxicity as evidenced by decreases in serum ALT levels as well as the inflammatory cytokine TNF-α and the lipid peroxidation product MDA.

Glycyrrhizin and mannitol synergistically decreased alcohol-induced production of reactive oxygen species (ROS) by enhancing the levels of the enzymes that decompose tissue damaging ROS, namely catalase, GPX and SOD[14]. Reduced glutathione (GSH) is the primary antioxidant within cells that protects against ROS. Alcohol consumption results in a depletion of GSH as a result of the alcohol-induced production of ROS. Concurrent consumption of the combination of mannitol and glycyrrhizin (NTX) provided significant restoration of endogenous GSH levels in the liver[14], indicative of a more normal healthy functioning liver.

A study was conducted in rats that evaluated the effects of NTX on oxidative stress induced by a single dose of alcohol[18]. The alcohol alone increased hepatic production of ROS, decreased GSH and increased MDA, all indicators of alcohol-induced toxicity. Co-administration of NTX with the alcohol significantly modulated these alcohol-induced effects indicating a hepatoprotective effect of the NTX.

Another study in rats evaluated the hepatoprotective effects of NTX against alcohol induced hepatotoxicity[19]. Rats were given ethanol daily for 28 days with and without NTX. Alcohol treatment resulted in an elevation of the serum enzymes ALT, AST, GGT and ALP, denoting hepatic toxicity. In addition, the lipid peroxidation product MDA was elevated while the endogenous antioxidant GSH was decreased. Co-administration of NTX with the alcohol resulted in 20-40 % decreases in the levels of ALT, AST, GGT and ALP, demonstrating the hepatoprotective effects of the NTX. Furthermore, significant decreases occurred in alcohol-induced lipid peroxidation (MDA) with significant increases in the antioxidant and tissue protectant GSH, demonstrating the liver protective effects of NTX. The hepatoprotective effects of NTX in this rat study were confirmed by histopathological examination that showed a marked reduction in alcohol-induced lesions with an absence of necrotic cells[19].

A study has examined the beneficial effects of a glycyrrhizin product on alcohol-induced fibrosis in rats[21]. Pathological liver fibrosis was observed when rats were treated daily with alcohol for 16 weeks. Fibrosis was assessed and demonstrated by measuring serum levels of hyaluronic acid, laminin, procollagen III and collagen type IV as well as histopathology. All indices of fibrosis were significantly decreased in rats co-administered the glycyrrhizin product, thus demonstrating that the glycyrrhizin exhibits tissue protective effects and supports normal liver function[21].

A study in rats has examined the inhibitory effects of glycyrrhizin on alcohol plus carbon tetrachloride-induced liver cirrhosis[22]. The alcohol plus carbon tetrachloride significantly increased serum ALT and the inflammatory marker NF-κB, and histologically liver steatosis and fibrosis were severe. Co-treatment with a glycyrrhizin product markedly improved the steatosis and fibrosis, significantly reduced the serum ALT levels and returned the NF-κB levels to near normal. The authors concluded that the glycyrrhizin protected the liver from hepatotoxin-induced liver injury and cirrhosis[22].

A published meta-analysis of 12 randomized controlled trials (RCTs) has summarized the effects of a glycyrrhizin product on liver function in 838 patients with alcoholic liver disease[53]. The analysis showed that glycyrrhizin significantly decreased serum ALT and AST levels, and the authors concluded that the glycyrrhizin product significantly improved liver function in alcoholic liver disease[53].

A published meta-analysis of 9 randomized controlled trials involving 687 patients with chronic hepatitis treated with diammonium glycyrrhizinate, a salt of glycyrrhizin, concluded that the diammonium glychrryizinate significantly decreased serum ALT and AST levels[68]. Furthermore, the treatment provided significant improvements in total bilirubin and albumin, thus demonstrating improved liver function.

Another meta-analysis reviewed 24 randomized control trials involving 3201 patients with chronic hepatitis who were treated with diammonium glycyrrhizinate[69]. The authors concluded that the diammonium glycyrrhizinate significantly reduced serum ALT and total bilirubin and ameliorated fibrosis, therefore supporting normal liver function.

REDUCES THE RISK OF LIVER DISEASES INDLUDING FIBROSIS AND CIRRHOSIS

Alcoholic liver disease exhibits a histopathological progression that ranges from steatosis to more advanced stages as steatohepatitis, cirrhosis, hepatocellular carcinoma and liver failure due to necrosis or apoptosis (programmed cell death)[3,4]. Common biomarkers used to assess the progression of alcoholic liver damage and disease included the measurement of serum levels of the enzymes ALT, AST, GGT and ALP[50-52]. Other biomarkers that are also used to determine the degree of tissue damage and impairment of liver function include total bilirubin, lipid profiles, hemoglobin or serum ferritin, albumin, and platelets.

Numerous human and animal studies have demonstrated that NTX and its individual components glycyrrhizin and mannitol support normal defense mechanisms and preclude alcohol liver diseases including fibrosis and cirrhosis, thereby allowing normal function and regeneration of the liver.

A randomized, double-blind, placebo-controlled cross-over clinical trial has demonstrated that NTX provides significant liver protection during 12 days of alcohol consumption as compared to receiving alcohol alone as evidenced by decreases and normalization of the hepatic enzyme biomarkers of liver toxicity ALT, AST, GGT and ALP[15]. A four week washout period was provided between the cross-over treatments.

Another randomized, double-blind, placebo-controlled cross-over clinical trial involving human 31 subjects was conducted whereby all participants received a single dose alcohol with and without NTX. A seven day washout was provided between cross-over treatments[16]. Alcohol alone resulted in an increase in serum ROS and ROS metabolites, a decrease in serum GSH, an increase in MDA, an increase in protein carbonyl, and an increase in DNA damage in peripheral lymphocytes as determined by the single cell electrophoresis comet assay, the cytokinesis-block micronucleus assay, and 8-hydroxy-2-deoxyguanosine formation. Consumption of alcohol with NTX significantly reduced the levels of ROS and all the oxidative markers and increased serum GSH. The results indicated that NTX may "be effective in reducing alcohol-induced pathophysiological changes"[16].

Glycyrrhizin, one of the two active constituents in NTX, has been shown in a number of clinical studies to significantly reduce and normalize serum ALT and AST in patients with chronic hepatitis[54-67]. The frequency of ALT normalization was dependent upon duration of glycyrrhizin administration, with the highest normalization being approximately 35 %[54].

Animal studies have demonstrated that NTX provides significant protection against alcohol-induced oxidative damage to the liver as evidenced by decreases

and normalization of the serum levels of ALT, AST, GGT and ALP[14,19]. The combination of glycyrrhizin and mannitol, the active ingredients in NTX, synergistically decreased alcohol induced production of reactive oxygen species (ROS) by enhancing the levels of the enzymes catalase, GPX and SOD that decompose tissue damaging ROS[14], thus contributing to the maintenance of normal liver function. In addition, consumption of mannitol and glycyrrhizin (NTX) prevented alcohol-induced depletion of endogenous GSH levels in the liver[14], indicative of hepatoprotection by NTX and a normal healthy functioning liver.

The ability of NTX to protect against alcohol induced hepatotoxicity was evaluated in rats[19]. Rats were given ethanol daily for 28 days with and without NTX. Alcohol treatment produced an elevation of serum enzymes ALT, AST, GGT and ALP, while the endogenous antioxidant GSH was decreased, denoting hepatic toxicity. Co-administration of NTX with the alcohol resulted in 20-40 % decreases in the levels of ALT, AST, GGT and ALP with significant increases in the intracellular antioxidant and tissue protectant GSH, demonstrating the ability of NTX to significantly decrease the hepatotoxic effects of alcohol. Histopathological examination confirmed that NTX decreased alcohol-induced damage to the liver and resulted in a lack of alcohol-induced necrotic cells[19].

A published meta-analysis has summarized the effects of a glycyrrhizin product on liver function in 838 patients with alcoholic liver disease involving 12 randomized controlled trials (RCTs)[53]. Glycyrrhizin administration significantly decreased serum ALT and AST levels, and the authors concluded that the glycyrrhizin product significantly improved liver function in alcoholic liver disease[53].

A published meta-analysis of 9 randomized controlled trials involving 687 patients with chronic hepatitis treated with diammonium glycyrrhizinate, a salt of glycyrrhizin, demonstrated that the diammonium glychrryizinate significantly decreased serum ALT and AST levels[68]. Furthermore, the treatment provided significant improvements in total bilirubin and albumin, thus demonstrating a reduction in the effects of the hepatitis and an improvement in liver function.

A meta-analysis reviewed 24 randomized control trials involving 3201 patients with chronic hepatitis who were treated with diammonium glycyrrhizinate[69]. The diammonium glycyrrhizinate significantly reduced serum ALT and total bilirubin and ameliorated fibrosis, therefore supporting normal liver function.

A study in rats has evaluated the hepato-protective effects of NTX against alcohol induced hepatotoxicity[19.]. Rats were given ethanol daily for 28 days with and without NTX. Alcohol treatment resulted in an elevation of the serum enzymes ALT, AST, GGT and ALP, denoting liver toxicity. In addition, the lipid peroxidation product MDA was significantly elevated while the endogenous antioxidant GSH was decreased as a result of the alcohol treatment. Co-administration of NTX with the alcohol resulted in 30-48 % decreases in the levels of ALT, AST, GGT and ALP, demonstrating the hepatoprotective effects of the NTX. Furthermore, a 61 % decrease occurred in lipid peroxidation (MDA) with over a 50 % increase in GSH, demonstrating the liver protective effects of NTX.

The beneficial effects of a glycyrrhizin product on alcohol-induced fibrosis in rats have been studied[21]. Pathological liver fibrosis occurred when rats were treated daily with alcohol for 16 weeks. Fibrosis was assessed and demonstrated by measuring serum levels of hyaluronic acid, laminin, procollagen III and collagen type IV as well as histopathology. All indices of fibrosis were significantly decreased in rats co-administered the glycyrrhizin product, demonstrating that glycyrrhizin exhibits tissue protective effects and supports normal liver function[21].

Glycyrrhizin has been shown to inhibit alcohol plus carbon tetrachloride-induced liver cirrhosis in rats[22]. Alcohol plus carbon tetrachloride significantly increased serum ALT and the inflammatory marker NF-κB, while histologically liver steatosis and fibrosis were observed to be severe. Co-treatment with a glycyrrhizin product markedly improved the steatosis and fibrosis, significantly reduced the serum ALT levels and returned the NF-κB levels to near normal. The authors noted that the glycyrrhizin “protects liver from hepatotoxin-induced liver injury and cirrhosis”[22].

Magnesium isoglycyrrhizinate, a magnesium salt form of glycyrrhizin, improves liver function in humans with alcoholic liver[70], disease chronic hepatitis[71,72], cirrhosis[73] as demonstrated by decreases in the serum levels of ALT, AST and total bilirubin. These results have been confirmed in rats with non-alcoholic steatohepatitis[74] and mice with acute hepatic injury[75] treated with magnesium isoglycyrrhizinate based on serum measurements of AST, ALT, MDA, lipid profiles and TNF-α as well as liver histopathology.

AMELIORATES THE SYMPTOMS ASSOCIATED WITH LIVER DISEASE INCLUDING FIBROSIS AND CIRRHOSIS

The histopathological progression of alcoholic liver disease ranges from steatosis to more advanced stages as steatohepatitis, cirrhosis, hepatocellular carcinoma and liver failure due to necrosis or apoptosis (programmed cell death)[3,4]. Biomarkers are commonly used to assess the progression of alcoholic liver damage and disease that include measurement of serum levels of the enzymes ALT, AST, GGT and ALP[50-52]. Biomarkers that are also used to determine the degree of tissue damage as hepatitis, fibrosis and cirrhosis include total bilirubin, lipid profiles, hemoglobin or serum ferritin, albumin, and platelets.

Numerous human and animal studies have demonstrated that NTX and its individual components glycyrrhizin and mannitol support normal defense mechanisms and ameliorate liver diseases including fibrosis and cirrhosis, thereby facilitating normal function and regeneration of the liver.

NTX co-administration with alcohol has been shown to provide significant decreases and normalization in the enzyme biomarkers of liver toxicity ALT, AST, GGT and ALP[15]. A randomized, double-blind, placebo-controlled cross-over clinical trial involving 12 human subjects received alcohol daily for 12 days or alcohol in combination with NTX. A four week washout cross-over period was provided. The results demonstrated that NTX suppressed alcohol toxicity and helped maintain normal liver function.

A second randomized, double-blind, placebo-controlled cross-over clinical trial involving human 31 subjects was conducted whereby all participants received 1.5 g alcohol/kg with and without NTX. A seven day washout was provided between treatments[16]. Alcohol alone caused an increase in serum ROS and ROS metabolites, a decrease in serum GSH, an increase in MDA, an increase in protein carbonyl, and an increase in DNA damage in peripheral lymphocytes as determined by the single cell electrophoresis comet assay, the cytokinesis-block micronucleus assay, and 8-hydroxy-2-deoxyguanosine formation. Consumption of alcohol in combination NTX significantly reduced the levels of ROS and all the oxidative markers. The results indicated that NTX may "be effective in reducing alcohol-induced pathophysiological changes"[16].

Glycyrrhizin, one of the two active constituents in NTX, has been shown in a number of clinical studies to significantly reduce and normalize serum ALT and AST in patients with chronic hepatitis[54-67]. The frequency of ALT normalization was dependent upon duration of glycyrrhizin administration, with the highest normalization being approximately 35 %[54].

A meta-analysis has summarized the effects of a glycyrrhizin product on liver function in 838 patients with alcoholic liver disease involving 12 randomized controlled trials (RCTs)[53]. Glycyrrhizin administration significantly decreased serum ALT and AST levels. The authors concluded that the glycyrrhizin product significantly improved liver function in alcoholic liver disease, thus ameliorating the symptoms associated with the disease[53].

Animal studies have demonstrated that NTX provides significant protection against alcohol-induced oxidative damage to the liver as evidenced by decreases in the serum levels of ALT, AST, GGT and ALP[14,19]. Oxidative liver damage ultimately leads to hepatitis, fibrosis and cirrhosis. The combination of glycyrrhizin and mannitol, the active ingredients in NTX, synergistically decreased alcohol induced production of reactive oxygen species (ROS) by enhancing the levels of the enzymes catalase, GPX and SOD that decompose tissue damaging ROS[14], thus

contributing to the maintenance of normal liver function. In addition, consumption of mannitol and glycyrrhizin (NTX) prevented alcohol-induced depletion of endogenous GSH levels in the liver[14], indicative of hepato-protection by NTX and contributing to a normal healthy functioning liver.

A study in rats evaluated the ability of NTX to protect against alcohol induced hepatotoxicity[19.]. Rats were given ethanol daily for 28 days with and without NTX. Alcohol treatment elevated serum enzymes ALT, AST, GGT and ALP, denoting liver toxicity. In addition, serum levels of the endogenous antioxidant GSH decreased. Co-administration of NTX with the alcohol resulted in 20-40 % decreases in the levels of ALT, AST, GGT and ALP with significant increases in GSH, demonstrating the ability of NTX to significantly decrease the hepatotoxic effects of alcohol. . Histopathological examination confirmed that NTX decreased alcohol-induced damage to the livers of these rats and resulted in a lack of alcohol-induced necrotic cells[19].

A published meta-analysis of 9 randomized controlled trials involving 687 patients with chronic hepatitis treated with diammonium glycyrrhizinate, a salt of glycyrrhizin, demonstrated that the diammonium glychrryizinate significantly decreased serum ALT and AST levels[68]. Furthermore, the treatment provided significant improvements in total bilirubin and albumin, thus demonstrating a significant amelioration of the hepatitis in terms of liver function.

A meta-analysis reviewed 24 randomized control trials involving 3201 patients with chronic hepatitis who were treated with diammonium glycyrrhizinate[69]. The diammonium glycyrrhizinate reduced significantly serum ALT and total bilirubin, and ameliorated fibrosis, therefore supporting normal liver function.

The beneficial effects of a glycyrrhizin product on alcohol-induced fibrosis in rats have been studied[21]. Pathological liver fibrosis occurred when rats were treated daily with alcohol for 16 weeks. Fibrosis was assessed and demonstrated by measuring serum levels of hyaluronic acid, laminin, procollagen III and collagen type IV as well as liver histopathology. All indices of fibrosis were significantly

decreased in rats co-administered the glycyrrhizin product, demonstrating that glycyrrhizin exhibits tissue protective effects and ameliorates alcohol-induced liver fibrosis[21].

Glycyrrhizin has been shown to inhibit alcohol plus carbon tetrachloride-induced liver cirrhosis in rats[22]. Alcohol plus carbon tetrachloride significantly increased serum ALT and the inflammatory marker NF-κB, while histologically liver steatosis and fibrosis were observed to be severe. Co-treatment with a glycyrrhizin product markedly ameliorated the steatosis and fibrosis, significantly reducing the serum ALT levels and returning the NF-κB levels to near normal. The authors noted that the glycyrrhizin "protects liver from hepatotoxin-induced liver injury and cirrhosis"[22].

Studies have shown that magnesium isoglycyrrhizinate, a magnesium salt form of glycyrrhizin, improves liver function in humans with alcoholic liver[70], disease chronic hepatitis[71,72], cirrhosis[73] as demonstrated by decreases in the serum levels of ALT, AST and total bilirubin. These results have been confirmed in rats with non-alcoholic steatohepatitis[74] and mice with acute hepatic injury[75] treated with magnesium isoglycyrrhizinate based on serum measurements of AST, ALT, MDA, lipid profiles and TNF-α as well as liver histopathology.

HELPS MAINTAIN NORMAL LIVER FUNCTIONS

Common biomarkers used to assess liver function and disease include the measurement of blood levels of the enzymes ALT, AST, GGT and ALP[50-52]. Other biomarkers that are used to determine the degree of tissue damage and impairment of liver function include total bilirubin, lipid profiles, hemoglobin or serum ferritin, albumin, and platelets.

Numerous human and animal studies have demonstrated that NTX and its individual components glycyrrhizin and mannitol support normal defense

mechanisms and preclude oxidative tissue damage and inflammation, thereby allowing normal function of the liver.

The co-administration of NTX with alcohol significantly decreases and normalizes the enzyme biomarkers of liver toxicity ALT, AST, GGT and ALP[15], documenting the hepatoprotective effects of the NTX. A randomized, double-blind, placebo-controlled cross-over clinical trial involving 12 human subjects received alcohol daily for 12 days with or without NTX. A four week washout cross-over period was provided between treatments. NTX decreased the biomarkers of toxicity and demonstrated that NTX suppressed alcohol toxicity and helped maintain normal liver function.

A second randomized, double-blind, placebo-controlled cross-over clinical trial involving human 31 subjects was conducted whereby all participants received a single dose of alcohol with and without NTX. A seven day washout was provided between treatments[16]. Alcohol alone increased serum ROS and ROS metabolites, decreased serum GSH, increased MDA, increased protein carbonyl, and increased DNA damage in peripheral lymphocytes. Consumption of alcohol in combination NTX significantly reduced the levels of ROS and all the oxidative markers. The results indicated that NTX may "be effective in reducing alcohol-induced pathophysiological changes"[16], helping to maintain normal liver function.

Glycyrrhizin, one of the two active constituents in NTX, has been shown in a number of clinical studies to significantly reduce and normalize serum ALT and AST in patients with chronic hepatitis[54-67]. The frequency of ALT normalization was dependent upon duration of glycyrrhizin administration, with the highest normalization being approximately 35 %[54].

A meta-analysis summarized the effects of a glycyrrhizin product on liver function in 838 patients with alcoholic liver disease involving 12 randomized controlled trials (RCTs)[53]. Glycyrrhizin administration significantly decreased serum ALT and AST levels. The authors concluded that the glycyrrhizin product significantly improved liver function in alcoholic liver disease[53].

Animal studies have demonstrated that NTX provides significant protection against alcohol-induced oxidative damage to the liver as evidenced by normalization of the serum levels of ALT, AST, GGT and ALP[14,19]. Rats were given ethanol daily for 28 days with and without NTX[19]. Alcohol treatment produced an elevation of serum enzymes ALT, AST, GGT and ALP, while the endogenous antioxidant GSH was decreased, denoting liver toxicity. Co-administration of NTX with the alcohol resulted in 20-40 % decreases in the levels of ALT, AST, GGT and ALP with 24-28 % increases in the levels of the antioxidant and tissue protectant GSH, demonstrating the ability of NTX to significantly decrease the hepatotoxic effects of alcohol. Histopathological examination confirmed that NTX decreased alcohol-induced damage to the liver and resulted in a lack of alcohol-induced necrotic cells[19].

Oxidative liver damage ultimately leads to hepatitis, fibrosis and cirrhosis. The combination of glycyrrhizin and mannitol, the active ingredients in NTX, synergistically decreased alcohol induced production of reactive oxygen species (ROS) by enhancing the levels of the enzymes catalase, GPX and SOD that decompose tissue damaging ROS[14], thus contributing to the maintenance of normal liver function. In addition, consumption of mannitol and glycyrrhizin (NTX) prevented alcohol-induced depletion of endogenous GSH levels in the liver[14], indicative of hepato-protection by NTX and contributing to a normal healthy functioning liver.

A published meta-analysis of 9 randomized controlled trials involving 687 patients with chronic hepatitis treated with diammonium glycyrrhizinate, a salt of glycyrrhizin, demonstrated that the diammonium glychrryizinate significantly decreased serum ALT and AST levels[68]. Furthermore, the treatment provided significant improvements in total bilirubin and albumin, thus demonstrating an amelioration of the symptoms of the hepatitis and an improvement in liver function.

A meta-analysis reviewed 24 randomized control trials involving 3201 patients with chronic hepatitis who were treated with diammonium glycyrrhizinate[69]. The diammonium glycyrrhizinate reduced significantly serum ALT and total bilirubin, and ameliorated fibrosis, therefore supporting normal liver function.

A licorice extract predominantly containing glycyrrhizin has been shown to effectively inhibit alcohol induced fatty liver disease as exemplified by increases increases in ALT and AST, increases in TNF-α, lipid accumulation in liver (steatosis) and decreases in the antioxidant GSH[20]. The hepatoprotective effect of the glycyrrhizin preparation was confirmed histologically.

The effects of a glycyrrhizin product on alcohol-induced liver fibrosis in rats have been studied[21]. Pathological liver fibrosis occurred when rats were treated daily with alcohol for 16 weeks. Fibrosis was assessed and demonstrated by measuring serum levels of hyaluronic acid, laminin, procollagen III and collagen type IV as well as histopathology. All indices of fibrosis were significantly decreased in rats co-administered the glycyrrhizin product, demonstrating that glycyrrhizin exhibits tissue protective effects and helps normalize liver function[21].

Glycyrrhizin has been shown to inhibit alcohol plus carbon tetrachloride-induced liver cirrhosis in rats[22]. Alcohol plus carbon tetrachloride significantly increased serum ALT and the inflammatory marker NF-κB, while histologically liver steatosis and fibrosis were observed to be severe. Co-treatment with a glycyrrhizin product markedly ameliorated the steatosis and fibrosis, significantly reducing the serum ALT levels and returning the NF-κB levels to near normal. The authors noted that the glycyrrhizin "protects liver from hepatotoxin-induced liver injury and cirrhosis"[22].

Glycyrrhizin ameliorates oxidative liver damage associated with high fructose intake in rats[38]. Glycyrrhizin administration significantly normalized levels of AST, ALT, ALP, ROS, carbonyl protein, lipid peroxidation (MDA) and apoptosis, all characteristic of oxidative liver damage. The tissue protective effects of the glycyrrhizin and normalization of liver function were affirmed histologically[38].

In cell culture experiments, glycyrrhizin has been shown to inhibit TNF-α secretion[30,31] and MDA production[32-34], while enhancing the antioxidant enzyme SOD and the antioxidant GSH[32,33,35]. These results provide supporting evidence of the ability of glycyrrhizin to promote normal liver function.

Mannitol is the second of the two primary components of NTX. Several human studies have demonstrated the antioxidant and tissue protective effects of mannitol. Mannitol has been shown to exhibit tissue protective effects in acute ischemic-reperfusion injuries[45], and antioxidant and free radical scavenging properties in conjunction with cardiopulmonary bypass[46]. Mannitol is used as an anti-inflammatory and antioxidant in tissue baths associated with kidney transplants[47].

In a study in rats, mannitol was demonstrated to provide protection against alcohol-induced gastric mucosal damage due to its antioxidant and anti-inflammatory properties[48]. Mannitol has also been shown to exhibit anti-inflammatory and antioxidant activity in rats after traumatic brain injury[49]. Mannitol decreased production of MDA and normalized the levels of the antioxidant enzymes catalase and GPx.

HELPS PROTECT DNA FROM ALCOHOL-INDUCED DAMAGE

The metabolism of alcohol in the liver results in the production of reactive oxygen species (ROS) that produce DNA damage including strand breaks and fragmentation as well as damage to other tissue components[76, 77]. ROS can also activate or repress epigenetic elements as chromatin remodeling, micro-RNAs, DNA (de)methylation and histone modification that affect gene expression, thereby leading to various liver disorders[77,78]. Furthermore, ethanol is metabolically activated to free radical species that form adducts with DNA, precluding the formation of various proteins essential for healthy liver function[79,80]. Various human, animal and in vitro studies have shown that NTX and it components glycyrrhizin and mannitol can protect against the formation of DNA damage induced by alcohol and other agents.

A randomized, double-blind, placebo-controlled cross-over clinical trial involving human 31 subjects was conducted whereby all participants received alcohol with and without NTX. A seven day cross-over washout was provided between treatments[16]. Consumption of alcohol alone caused an increase in DNA damage in peripheral lymphocytes as determined by the single cell electrophoresis comet assay, the cytokinesis-block micronucleus assay, and 8-hydroxy-2-deoxyguanosine formation. Co-consumption of alcohol with NTX significantly reduced the levels of DNA damage by protecting the DNA and preventing damage from occurring

Various studies using human and animal tissues have shown that glycyrrhizin can prevent oxidative damage to DNA. Incubation of human lymphocytes with oxidative mutagens as hydrogen peroxide prevented the formation of DNA damage by as much as 70 %[81]. Similarly, glycyrrhizin significantly decreases ROS-induced DNA damage in human epithelial cells as determined by a single cell gel electrophoresis assay[82]. Glycyrrhizin has also been shown to protect cellular DNA from radiation induced double strand breaks in human peripheral blood leukocytes and in peripheral blood leukocytes and bone marrow of mice by scavenging free radicals and reactive oxygen species[83].

In rat primary hepatocyte cultures, glycyrrhizin prevented peroxide-induced DNA fragmentation and modulated programmed cell death (apoptosis)[33]. Several studies in rats have demonstrated that glycyrrhizin ameliorates oxidative hepatic DNA damage associated with metabolic syndrome, thus demonstrating its therapeutic potential against hepatocellular damage[38,84]. In a rat study, glycyrrhizin has been referred to as a potent chemopreventive, preventing oxidative tissue damage and normalizing DNA synthesis and metabolism[85]. In mice, glycyrrhizin was shown to prevent oxidative stress-induced DNA fragmentation and micronucleus formation as well as maintaining normal tissue histology[86].

Mannitol, the other component in NTX in addition to glycyrrhizin, has also been shown to prevent DNA damage in cell culture and cell free systems. Mannitol has been demonstrated to prevent oxidative DNA damage in vitro systems involving

normal human keratinocytes[87,88]. Mannitol was an effective scavenger of ROS and an effective inhibitor of oxidative DNA damage. Mannitol in Chinese hamster ovary (CHO) cells in culture stabilizes DNA and prevents DNA single and double strand breaks[88-90]. Mannitol provided significant inhibition of copper and iron induced DNA damage in isolated rat hepatic nuclei[91]. Mannitol has also been shown to prevent DNA damage associated with various ROS generating agents in in vitro cell-free systems[92-94].

The above studies show that NTX as well as its primary components glycyrrhizin and mannitol can prevent DNA damage as DNA single and double strand breaks induced by alcohol and other ROS generating systems in liver and other tissues. The animal and in vitro studies corroborate the human studies with NTX, and provide information regarding the mechanism of action its primary components.

REDUCES ALCOHOL-INDUCED DNA DAMAGE

Hepatic metabolism of alcohol results in the production of reactive oxygen species (ROS) that induce DNA damage including strand breaks and fragmentation as well as damage to other tissue components[76, 77]. ROS can also modulate epigenetic elements as chromatin remodeling, micro-RNAs, DNA (de)methylation and histone modification that affect gene expression, thereby leading to various liver disorders[77,78]. Ethanol is also metabolically activated to free radical species that form adducts with DNA, thereby inhibiting DNA and normal healthy liver function[79,80]. Human, animal and in vitro studies have shown that NTX and it components glycyrrhizin and mannitol can reduce the formation of DNA damage induced by alcohol and other ROS-generating agents, thus affording tissue and organ protection.

A randomized, double-blind, placebo-controlled cross-over clinical trial involving human 31 subjects was conducted whereby all participants received alcohol with and without NTX. A seven day cross-over washout was provided between treatments[16]. Consumption of alcohol alone caused an increase in DNA damage in peripheral lymphocytes as determined by the single cell electrophoresis comet

assay, the cytokinesis-block micronucleus assay, and 8-hydroxy-2-deoxyguanosine formation. Consumption of alcohol with NTX significantly reduced the levels of DNA damage.

Human and animal tissue studies have shown that glycyrrhizin, a primary component in NTX, can reduce oxidative damage to DNA. Incubation of human lymphocytes with oxidative mutagens as hydrogen peroxide reduced ROS formation of DNA damage by as much as 70 %[81]. In another study, glycyrrhizin significantly reduced ROS-induced DNA damage in human epithelial cells as determined by a single cell gel electrophoresis assay[82]. Glycyrrhizin reduces cellular DNA from radiation induced double strand breaks by scavenging free radicals and reactive oxygen species[83]. This ability of glycyrrhizin was demonstrated in peripheral blood leukocytes derived from humans and mice as well as bone marrow cells of mice[83].

In rat primary hepatocyte cultures, glycyrrhizin reduced peroxide (ROS)-induced DNA fragmentation and programmed cell death (apoptosis)[33]. Studies in rats have demonstrated that glycyrrhizin reduces ROS-induced hepatic DNA damage associated with metabolic syndrome, demonstrating its therapeutic potential against hepatocellular damage[38,84]. Glycyrrhizin also accelerates liver regeneration following partial hepatectomy and decreases elevated serum levels of ALT and AST, thus demonstrating ability of glycyrrhizin to enhance regeneration of liver mass and function[95]. One mechanism whereby glycyrrhizin reduces and inhibits oxidative DNA damage in tissues may be by the direct binding of glycyrrhizin to the major and minor grooves and phosphate backbone of DNA as has been shown in an in vitro model[96].

Mannitol, the other component in NTX in addition to glycyrrhizin, has also been shown to prevent DNA damage in cell culture and cell free systems. Mannitol has been demonstrated to reduce oxidative DNA damage in vitro systems involving normal human keratinocytes[87,88]. Mannitol was an effective scavenger of ROS and an effective inhibitor of oxidative DNA damage. Mannitol in Chinese hamster ovary (CHO) cells in culture stabilizes DNA and reduces DNA single and double

strand breaks[88-90]. Mannitol provided significant inhibition of DNA damage associated with copper and iron initiated oxidative stress in isolated rat hepatic nuclei[91]. Mannitol has also been shown to reduce DNA damage associated with various ROS generating agents in in vitro cell-free systems[92-94].

In summary, NTX and its primary components glycyrrhizin and mannitol can reduce DNA damage as DNA single and double strand breaks induced by alcohol and other ROS generating systems in liver and other tissues. In addition, a study in rats has demonstrated the ability of glycyrrhizin to restore function and enhance regeneration of the liver, a benefit that can be readily applied to chronic alcohol consumption and alcoholic liver disease.

SAFETY

Various studies have assessed the safety of NTX and its constituents, glycyrrhizin and mannitol. A randomized, double-blind, placebo-controlled cross-over clinical trial involving 12 human subjects received alcohol daily for 12 days or alcohol in combination with NTX. A four week washout cross-over period was provided. NTX co-administration with alcohol has been shown to provide significant decreases and normalization in the enzyme biomarkers of liver toxicity ALT, AST, GGT and ALP[15]. NTX had no effect on heart rate, blood pressures or respiratory rate, and no adverse effects were reported in these human subjects[15]. The results demonstrated that NTX suppressed alcohol toxicity while exhibiting no adverse effects under the experimental conditions employed in humans.

A 28 day NTX detailed safety study was conducted in rats[19]. Rats were orally administered 0, 0.5 gm/kg, 0.75 gm/kg, and 1.0 gm/kg NTX daily for 28 days. The rats were observed daily for visible signs of reaction to the NTX such as eye and mucus membrane changes, respiration, central nervous system, circulatory, somatomotor activity and behavioral patterns. No untoward changes were observed. Furthermore, no changes were observed with respect to body weights or food consumption.

Clinical pathology assessments were conducted on blood samples drawn prior to treatment at two weeks of treatment and at 28 days of treatment[19]. As compared to the untreated (vehicle only) controls, at no time points did NTX treatment at any of the three doses result in significant changes with respect to leukocyte count, erythrocyte count, lymphocyte count, monocyte count, eosinophil count, basophil count, hemoglobin, differential count, blood clotting time, packed cell volume, serum sodium and potassium, plasma AST, ALT, ALP, blood urea nitrogen (BUN), creatinine or total protein. Microscopic examination of the urine sediment of control and NTX treated groups did not reveal the presence of any epithelial casts, bacterial cells, erythrocytes or any other abnormalities at any of the time points over the 28 days of treatment[19].

Upon post-mortem examination at the end of the 28 days of the study, the NTX treated animals did not reveal any significant lesions with respect to vital organs including livers, lungs, hearts, kidneys, spleens and urinary bladders. In summary, the results of this detailed safety study in rats clearly demonstrate the safety of NTX over a range of doses when given daily for up to 28 days[19]. No adverse effects of any kind were observed.

The safety of glycyrrhizin and various salts and derivatives thereof has been extensively reviewed[97]. The oral LD50 for glycyrrhetinic acid, the aglycone of glycyrrhizin, was 610 mg/kg or higher in rats and mice. Based on the differences in molecular weights, an equivalent amount of glycyrrhizin would be over 1.1 g/kg in rats which would be over 14.2 grams for an 80 kg human. For the sake of comparison, the LD50 for caffeine is believed to be in the range of about 10 grams in humans. In an 8 week study involving 39 healthy volunteers, the no effect level was conservatively determined to be 2 mg/kg/day or 160 mg for an 80 kg individual. Glycyrrhizin was shown to be non-phototoxic, Glycyrrhizate salts were non-carcinogenic in mice, and exhibited no reproductive or developmental toxicities in rats, mice, hamsters or rabbits[97].This detailed report concluded that glycyrrhizin and its salts exhibited little acute, short-term, subchronic or chronic toxicity[97].

Ingestion of glycyrrhizin at high doses can have physiological effects including sodium and water retention, potassium loss, weight gain and increased blood pressure. However, studies have been conducted where subjects have been given 300-700 mg glycyrrhizin per week for up to 16 years without significant adverse effects[54,98]. Under the conditions of use of NTX, the consumption of glycyrrhizin would be below the levels required to produce these adverse events.

A review has summarized the use of glycyrrhizin in the treatment of liver diseases[99]. Ten clinical studies are reviewed using doses up to 200 mg per day, primarily given intravenously. Six of the 10 studies reported no adverse effects, including a study that averaged approximately 10 years. Hypertension with skin rash was reported in one study that lasted for up to 14.5 years and involved daily intravenous injections which results in much higher blood and tissue levels than achieved by oral administration due to the gastro-intestinal metabolism of glycyrrhizin. Two studies reported headache and three studies reported an increase in blood pressure[99], which cannot be correlated with similar doses given orally.

Numerous plants and fungi produce mannitol, and as a consequence, mannitol is a common sugar alcohol present in the diet of human[100]. The subchronic oral toxicity of mannitol was studied in rats that were given approximately 12 grams of mannitol per kg per day for 90 days[101]. This dose would be equivalent to an 80 kg individual consuming about 155 grams of mannitol per day. The authors concluded that mannitol did not produce signs of toxicity.

The patent for NTX notes that glycyrrhizin is used at a concentration of 0.05-0.3 % while mannitol is used in the range of 0.5-3.0 %[14]. For someone consuming 60 ml of an alcoholic beverage (4 shots) containing NTX, they would consume 30-180 mg of glycyrrhizin and 300 mg-1.80 grams of mannitol, amounts that are clearly within the safety ranges for both ingredients.

CONCLUSIONS

The adverse health effects and societal costs of chronic and heavy alcohol consumption are well documented, and alcohol is a risk factor or cause of numerous diseases with alcoholic liver disease being the most common problem associated with chronic alcohol consumption. As a consequence, there is a pressing need to develop strategies for safer alcohol consumption and treatment in order to reduce alcohol-associated morbidity and mortality, and the high cost to society.

NTX is a patented product composed of the primary ingredients glycyrrhizin and mannitol that act synergistically. Based on the totality of the scientific information and evidence, NTX and its active ingredients glycyrrhizin and mannitol are safe and exhibit beneficial properties with respect to the potentially detrimental effects of alcohol. Therefore, health claims regarding NTX have been set forth, and each health claim is substantiated and extensively supported by the scientific literature.

CURRICULUM VITAE

S.J. STOHS, Ph.D.

Birth: Ludell, Kansas USA

EDUCATIONAL BACKGROUND:

Secondary School	- Scribner Public High School, Graduated 1957
B.S. in Pharmacy	- The University of Nebraska, Lincoln, 1962
M.S. in Natural Products and Biochemistry	- The University of Nebraska, Lincoln, 1964
Ph.D. in Biochemistry	- The University of Wisconsin, Madison, 1967
Post-Graduate Study	- Karolinska Institute, Stockholm, Sweden, 1975-76
	- National Institute of Environmental Health Sciences Research Triangle Park, NC 1987-88

PHARMACY LICENSE:

Nebraska

ACADEMIC APPOINTMENTS:

Assistant Professor, Department of Pharmacognosy, University of Nebraska, September 1967.

Assistant Professor and Acting Chairman, Department of Pharmacognosy, University of Nebraska, September 1968.

Member of the Graduate Faculty, University of Nebraska, June 1969.

Chairman, Department of Pharmacognosy, University of Nebraska, September 1970.

Associate Professor and Chairman (tenured), Department of Pharmacognosy, University of Nebraska, September 1971.

Associate Professor and Chairman, Department of Medicinal Chemistry and Pharmacognosy, University of Nebraska, September 1972.

Professor and Chairman, Department of Medicinal Chemistry and Pharmacognosy, University of Nebraska Medical Center, July 1974.

Leave of Absence from the University of Nebraska, and Visiting Research Associate, Department of Forensic Medicine, Karolinska Institute, Stockholm, Sweden, 1975 - 76.

Professor and Chairman, Department of Biomedicinal Chemistry, University of Nebraska Medical Center, August 1977.

Professor, Eppley Institute, February 1982.

Assistant Dean for Graduate Studies and Research, College of Pharmacy, Professor, Pharmaceutical Sciences and Eppley Institute, University of Nebraska Medical Center, November 1985.

Professor, Pharmaceutical Sciences and Eppley Institute, University of Nebraska Medical Center, July 1987 - January 1989.

Faculty Development Leave from University of Nebraska, and Visiting Professor, Systemic Toxicology Branch, National Institute of Environmental Health Sciences, Research Triangle Park, North Carolina, September 1987 through June, 1988.

Assistant Dean for Research and Professor, School of Pharmacy and Allied Health Professions, and Professor of Pharmacology, School of Medicine, Creighton University, January, 1989.

Acting Dean, School of Pharmacy and Allied Health Professions, Creighton University, October, 1990.

Dean, School of Pharmacy and Health Professions, Creighton University, July, 1991 - June, 2003.

Dean Emeritus, School of Pharmacy and Health Professions, Creighton University, July, 2003.

INDUSTRIAL APPOINTMENTS:

Senior Vice President of Research and Development, AdvoCare International, Carrollton, TX, October 2003 – 2009(retired). Responsible for development of over 25 new products and reformulation of over 40 products. New product development resulted in submitting 3 patent applications with one patent awarded and two pending.. Also had overall responsibility for product quality control/quality assurance, adverse events reporting, structure/function claims submitted to FDA, product training, clinical pilot studies on new and reformulated products, contract research studies regarding AdvoCare products, and audits of manufacturing facilities. In addition, interfaced with all other departments/areas, assisted in negotiation of product and raw material prices, and assisted in resolution of products/supply chain issues. Answered numerous distributor-related questions regarding ingredients, products and product applications.

Vice President for Scientific Affairs, AdvoCare International May 2014—January 1, 2015.

Kitsto Consulting LLC, Frisco, TX, January 2009 to present. Founding partner in consulting company specializing in toxicology, nutrition and wellness, research design and organizational analysis.

ADMINISTRATIVE EXPERIENCE:

Vice for Scientific Affairs, ADVOCARE International, May 2014-January 1, 2015.

Sr. Vice President of Research & Development, ADVOCARE International, 2003-2009(retired).

Responsible for the development of a research and development program, including the hiring of staff, and establishing operational policies and procedures. Overall responsibility for product development, product review and reformulation, quality assurance/quality control, regulatory affairs, adverse events,

documentation and records and good manufacturing practices for manufacturing facilities. Established research protocols for selected ADVOCARE products and identified research facilities. Member of supply chain team and product launch team. Extensive interface with distributors through product training presentations, email, AdvoLink and face-to-face interactions. Responsible for product training and participated in over 25 Success Schools since 1998.

Dean, School of Pharmacy and Allied Health Professions, Creighton University, 1991 –2003.

Program had 23 faculty members and six staff when position was assumed. In 2003, the School has over 100 faculty and approximately 45 staff. Developed the Doctor of Pharmacy degree as the sole professional degree. Initiated distance-learning Doctor of Pharmacy pathway for practitioners. Initiated the first entry-level Doctor of Physical Therapy and Doctor of Occupational Therapy programs in the country. Developed a post-professional Doctor of Occupational Therapy pathway. Initiated distance-learning pathways for the Doctor of Occupational Therapy and the Doctor of Physical Therapy for practitioners. Initiated a M.S. in Pharmaceutical Sciences. Initiated a Master of Health Services Administration program. Developed the nation's first web-based entry-level Doctor of Pharmacy pathway. Developed a B.S. program in Health Sciences for students in the Doctors of Pharmacy, Physical Therapy and Occupational Therapy Programs.

Acting Dean, School of Pharmacy and Allied Health Professions, Creighton University, 1990 – 1991.

Assistant Dean for Research, Creighton University, 1989 - 1990.

Assistant Dean for Research and Development, University of Nebraska Medical Center, 1986 - 1987.

Assistant Dean for Research and Graduate Education, University of Nebraska Medical Center, 1985 - 1986.

Chaired various committees at the campus, state and national levels including: Departmental Graduate Committee; College Policy and Procedures Committee; Pharmaceutical Sciences Area Graduate Committee; State Commission on Drugs, Education Subcommittee; UNMC Marshalling Corps; Faculty Senate Grievance Committee; AACP Biological Sciences Resolutions Committee; Academy of Pharmaceutical Sciences Kilmer Prize Committee; Program Committee, American Society of Pharmacognosy; Biological Sciences Section of AACP; AACP Biological Sciences Nominating Committee; Special Projects Grants Committee of AACP; University of Nebraska Chapter of Sigma Xi; and University wide Strategic Planning Subcommittee, Search Committees for Deans of School of Dentistry, School of Law and College of Business Administration.

Directed the research of over 40 graduate students, and the research and budgets

of over 60 grants and contracts.

Chairman of Department, 1968-85. Responsible for the budgets and programs of the Department of Biomedicinal Chemistry. Responsible for promotion and tenure recommendations, departmental budget, recommendations for faculty salaries and teaching assignments. The Department had 9 tenure track faculty (3 through Eppley), 4 additional adjunct faculty, 18 graduate students, one full-time secretary and additional secretarial assistance.

SOCIETY MEMBERSHIPS:

Sigma Xi, Rho Chi Pharmacy Honor Society, American Association of Colleges of Pharmacy, Drug Metabolism Group of the American Society for Pharmacology and Experimental Therapeutics, International Union of Pharmacology Section on Toxicology, International Society for the Study of Xenobiotics, Society of Toxicology, International Association of Biomedical Gerontology, Phi Lambda Sigma Leadership Honor Society, Phi Beta Delta Honor Society for International Scholars, American Pharmaceutical Association, Association of Schools of Allied Health Professions, American College of Nutrition, American Nutraceutical Association, Society of Free Radical Biology and Medicine, International Federation of Sports Medicine.

AWARDS AND HONORS:

B.S. in Pharmacy with Distinction, 1962; NIH Predoctoral Fellowship, 1962-64; NIH Trainee Fellowship, 1964-67; elected Sigma Xi, 1966; selected to participate in the American Association of Colleges of Pharmacy Visiting Lecturer's Program, 1972-73; major professor of the Outstanding Graduate Student at the University of Nebraska for 1973-74 (Ronald Talcott), for 1976-77 (Lester Reinke), and for 1979-80 (Walid Al-Turk) selected by Sigma Xi chapter; selected as an Outstanding Educator of American, 1975; listed in American Men and Women of Science, 1968-present; elected to membership into the American Society for Pharmacology and Experimental Therapeutics, 1976; selected to Notable Americans of 1976-77; Sigma Xi Outstanding Scientist Award for 1977-78 at University of Nebraska; University of Nebraska Medical Center Outstanding Teacher Award, 1981; President, University of Nebraska Chapter of Sigma Xi, 1984-85; Visiting Professor, Tanta University, Tanta, Egypt, April 1985; Alumni Faculty Award for Outstanding Research, 1985; 1985 APhA Foundation/APhA Academy of Pharmaceutical Sciences Research Achievement Award in Pharmacodynamics; 1988 Burlington Northern Faculty Achievement Award, University of Nebraska; American Association of Colleges of Pharmacy Teacher of the Year Award, 1987-88; Native Son Award, Scribner, NE, 1992; Phi Beta Delta, Honor Society for International Scholars, 1992; Phi Lambda Sigma Excellence in Leadership Award, Creighton University, 1994-95; Creighton University Black Employee Network Service Award, 1995; Nebraska Pharmacists Association Cora Mae Briggs Outstanding Service to Nebraska Pharmacy Award, 1996; Elected into Fellowship in the Academy of Toxicological Sciences (Fellow ATS), 1998 (recertified in 2003);

Honorary Member of the Turkish Clinical Pharmacy Society, 1998; Elected into Fellowship in the American College of Nutrition (Fellow ACN), 1999; Elected into Fellowship in the Association of Schools of Allied Health Professions (Fellow ASAHP, 1999); Holder, Gilbert F. Taffe, Jr. Endowed Chair, 2000-2003; National Multiple Sclerosis Corporate Achievers Award for Outstanding Leadership and Community Involvement, 2000; John Doull Award in Toxicology, Central States Chapter, Society of Toxicology, 2001; Certified Nutrition Specialist (CNS) by the Certification Board of the American College of Nutrition, 2002; Dean Emeritus, School of Pharmacy and Health Professions, Creighton University, 2003; American College of Nutrition Industrial Recognition Award, 2007; University of Nebraska Medical Center 2010 Distinguished Pharmacy Alumni Award; Fellowship in Americal Pharmacists Association (Fellow APhA, 2014).Excellence in Nutrition Science Award, Emord & Associates, 2014; Excellence in Integrative Medicine Award, Emord & Associates, 2014; Pharmacy Education Recognition Award, Fourth International Meeting of Pharmacy and Pharmaceutical Sciences, Istanbul, turkey, 2014.

DISSERTATIONS AND THESES DIRECTED:

1. Incorporation of 14C-Acetate into Khellin and Visnagin in *Ammi visnaga* Plants and Suspension Cultures. 1969. Min-Hsiu Chen, M.S.

2. The Production of Diosgenin and the Metabolism of 14C-Cholesterol by *Dioscorea deltoidea* Wall Tissue Cultures. 1969. Balkrishena Kaul, Ph.D.

3. The In Vitro Metabolism of ^{3}H-Digoxigenin. 1972. Ronald E. Talcott, M.S.

4. Studies of pH Effects on the Therapy of Chronic Urinary Tract Infections In Vivo. 1973. Victor A. Padron, M.S.

5. Phytochemical Studies on Tissue Cultures of *Withania somnifera*. 1973. Poli Chen Yu, M.S.

6. Some Aspects of Cardenolide Metabolism with Particular Reference to the Hepatic Microsomal NADPH-Dependent Mixed-Function Oxidase System. 1973. Ronald E. Talcott, Ph.D.

7. A Phytochemical Investigation of *Corchorus olitorius* and *C. capsularis* Tissue Cultures. 1974. Cindy Tarng, M.S.

8. The In Vitro and In Vivo Metabolism of H^3-Digitoxin and H^3-Digitoxigenin in the Rabbit and Some of the Related Aspects. 1974. William H. Bulger, Ph.D.

9. The Influence of Selected Sedative-Hypnotics on Mixed-Function Oxidases. 1975. Lester A. Reinke, M.S.

10. The Microencapsulation and Properties of Selected Drugs. 1975. Kedar Naik, Ph.D.

11. A Rapid In Vivo Preliminary Screening Technique in Mice for Antiarrhythmic Drugs. 1976. Peter Nwangwu, M.S.

12. Some Affects of Streptozotocin-Induced Diabetes on Hepatic Mixed-Function Monooxygenase Enzymes in Rats. 1977. Lester A. Reinke, Ph.D.

13. Hepatic Glutathione Levels in Diabetic Rats. 1977. Jeanne M. Hassing, M.S.

14. An Evaluation of Several Methods for the Determination of Catecholamines in Plasma. 1978. Glen A. Scratchley, M.S.

15. In Vitro Production of Estrone and Estriol from Selected Steroid Precursors in the Rabbit. 1978. Victor A. Padron, Ph.D.

16. Effects of Lithium Chloride on Aconitine-Induced Arrthythmias, Atrial and Ventricular Tachycardias, and on the Distribution of Selected Electrolytes and ATPases in the Mouse Heart. 1978. Oladipo Oredipe, M.S.

17. The Antiarrythmic Activities, Acute Toxicity Profile and Hemodynamic Properties of Some New and Selected Quinidine Analogs. 1979. Peter U. Nwangwu, Ph.D.

18. Some Aspects of Sex Dependent Regulation of Drug Metabolizing Enzymes in Hepatic and Extrahepatic Tissues. 1979. Walid A. Al-Turk, Ph.D.

19. The Effects of Chronic Inorganic Lead Poisoning on Erythrocyte 5'-Nucleotides in the Rabbit. 1979. Mark S. Swanson, M.S.

20. The Effects of Various Xenobiotics on Aryl Hydrocarbon Hydroxylase Activity of Intestinal and Hepatic Microsomes from Male Rats. 1981. Lin-Jau Wu, M.S.

21. The Synthesis and Preliminary in vitro Biological Evaluation of 5,8 Endoethano-3-hydroxy-N-methylmorphinan and Its Immediate Precursors. 1981. Victoria F. Roche, Ph.D.

22. Studies on the Effect of Intragastrically Administered 3-Methylcholanthrene on Intestinal Mixed-Function Oxidase Activity and Protein Synthesis. 1982. Jeanne Marie Hassing, Ph.D.

23. Effect of Diphenylhydantoin on Hepatic and Extrahepatic Mixed Function Oxidases in the Female Rat. 1982. Ronald J. Heinicke, M.S.

24. Changes in Glutathione and Glutathione Metabolizing Enzymes in Erythrocytes and Lymphocytes of Humans and Mice as a Function of Age. 1982. Fatma H. El-Rashidy, M.S.

25. Studies on Polyamine Decarboxylases, DNA Synthesis and Ultrastructural Alterations in 17-Estradiol-Stimulated Rat Target Organs and Estriol Antagonism. 1982. Lynn A. Lavia, Ph.D.

26. Percutaneous Absorption of Iodochlorhydroxyquin. 1983. Fikrat Wahbi Ezzedeen, Ph.D.

27. Some Biochemical Characteristics of Pyrimidine 5'-Nucleotidase Deficient Erythrocytes. 1983. Mark S. Swanson, Ph.D.

28. A Possible Role of Lipid Peroxidation in TCDD Toxicity. 1984. Mohammad Q. Hassan, Ph.D.

29. Biochemical and Toxicological Effects of 2,3,7,8-Tetrachlorodibenzo-p-dioxin Congeners in Female Rats. 1985. Mike A. Shara, M.S.

30. Lipid Peroxidation, Calcium, Iron and TCDD Toxicity in Rats. 1985. Zainab A.F. Al-Bayati, Ph.D.

31. Biochemical and Functional Effects of 2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD) on the Hearts of Female Rats. 1987. S.J. Hermansky, M.S.

32. Lipid Peroxidation Inducibility of Carbon Tetrachloride, Hexachlorocyclohexane, Dieldrin, Hexafluorobenzene and Hexachlorobenzene in Female Rats. 1987. M.R. Goel, M.S.

33. The Role of Divalent Cations in TCDD Induced Lipid Peroxidation and DNA Damage in Rats. 1988. Z.Z. Wahba, Ph.D.

34. Effects of TCDD on Lipid Peroxidation and Membrane Fluidity in the Mitochondria and Plasma Membranes of Rat Liver. 1988. N. Alsharif, M.S.

35. Effects of the Blue-Green Algal Hepatotoxin Microcystin-LR in Female Mice. 1990. S.J. Hermansky, Ph.D.

36. Evidence of 2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD)-Induced Oxidative Stress in Female Rats. 1990. M.A. Shara, Ph.D.

37. TCDD, Phagocytic Cells and Oxidative Stress. 1992. N.Z. Alsharif, Ph.D.

38. Mechanism of Ricin-Induced Oxidative Stress in Mice. 1995. Daniel F. Muldoon, Ph.D.

OTHER TRAINING ACTIVITIES:

Professional and undergraduate students who have received research training -
Naser Alsharif
Pat Casey
Phil Dickson
Julie Dopheide
Joseph Guzzo
Jeanette Haggerty
Joseph Hanna-Salem
Jeanne M. Hassing
Julia Kelly
Brian Knobel
Craig Kubitcek
Lon Lowry
Hamid Mohammadpour
Jeff Moser
Peter Nwangwu
John Obrist
Zeke Paster
Lester A. Reinke
Julie Sabatka
Sohel Sachek
Alan Smalljohn
Jorja Sturek
Philip Vuchetich
Christine Wagner
Bruce Weber
Vikki Miller
Kate Takacs

Post-doctoral fellows -
Dr. Paul Akubue
Dr. Hanan Al-Kaysi
Dr. Walid Al-Turk
Dr. Albert Awad
Dr. Debasis Bagchi
Dr. Manashi Bagchi
Dr. Laura Cook
Dr. Ezdihar Hassoun
Dr. Frank Luman
Dr. Rodney Markin
Dr. Zuhair Muhi-Eldeen
Dr. Gita Mukherjee

PATENTS:

U.S. patent 6,291,517 issued September 18, 2001 to D. Bagchi, M. Bagchi and S. J. Stohs on a “Method for preventing or reducing stress-induced gastric injury using grape seed proanthocyanidin extract.”

U.S. patent 7,645,742 issued January 12, 2010 to S. J. Stohs on “Composition for enhancing cellular energy” (Muscle fuel-AdvoCare International).

U.S. patent 7,989,009 issued August 2, 2011 to C. Kandaswami, S. J. Stohs and T. Coyle on “Composition and method for promoting weight loss”.

U.S. Patent 8.975,236 B2 issued March 10, 2015 to S. J. Stohs and H. Miller on “Dietary supplement composition of citrus derivatives”.

47. "Effect of Age on Tissue Glutathione Levels Activities of Mixed Function Monooxygenases and Hepatic Cytochrome P-450 Content in Mice." S.J. Stohs, W.A. Al-Turk, J.M. Hassing and F.M. Luman. American Society of Pharmacology and Experimental Therapeutics, 1980, Anaheim, California.

48. "Effect of Gonadectomy and Tamoxifen Treatment on Liver, Lung and Intestinal Mixed Function Monooxygenase Enzymes in the Rat." W.A. Al-Turk, S.J. Stohs and E.B. Roche. American Society of Pharmacology and Experimental Therapeutics, 1980, Anaheim, California.

49. "A Comparative Study on Some Hemodynamic Properties of Quinidine and Cupreidine (6'-hydroxycinchonine)." P.U. Nwangwu, T.L. Holcslaw, S.J. Stohs, H. Rosenberg and L.D. Small. American Society of Pharmacology and Experimental Therapeutics, 1980, Anaheim, California.

50. Effects of Lithium on Time to Onset of Aconitine-Induced Initial Arrhythmia and Ventricular Tachycardia, and on the Regional Myocardial Distribution of Lithium, Calcium and Potassium. S.J. Stohs. Annual Meeting, American Heart Association, Nebraska Affiliate, 1980, Kearney, Nebraska.

51. Effect of Hypophysectomy and Castration on Hepatic, Pulmonary and Intestinal Mixed Function Oxidases in the Rat. W.A. Al-Turk, S.J. Stohs, and E.B. Roch. American Society for Pharmacology and Experimental Therapeutics, 1980, Rochester, Minnesota.

52. Synthesis and Antiarrhythmic Activity of Three Quinidine Analogs. P.T. Tiwan, M.T. Tran, L.D. Small, H. Rosenberg and S.J. Stohs. Academy of Pharmaceutical Sciences, 1980, San Antonio, Texas.

53. Glutathione Reductase and Glutathione-S-transferase Activities in Hepatic and Extrahepatic Tissues of Mice with Age. S.J. Stohs, W.A. Al-Turk, and C.R. Angle. Society of Toxicology, 1981, San Diego, California.

54. Synthesis and Antiarrhythmic Activity of Five Quinidine Analogs. M.T. Tran, L.D. Small, H. Rosenberg and S.J. Stohs. Academy of Pharmaceutical Sciences, 1981, St. Louis, Missouri.

55. Analysis of Iodochlorhydroxyquin in Plasma Using High Performance Liquid Chromatography. F.W. Ezzedeen, A.M. Masoud, S.J. Stohs and S.J. Lerman. Academy of Pharmaceutical Sciences, 1981, St. Louis, Missouri.

56. Possible Role of Polyamines in Controlling Membrane Binding or Function of Ribosomes During Estrogen Stimulation. L.A. Lavia, H.M. Lemon and S.J. Stohs. The Endocrine Society, 1981, Cincinnati, Ohio.

57. Hepatic Glutathione Content and Aryl Hydrocarbon Hydroxylase Activity of Acetaminophen-treated Mice as a Function of Age. W.A. Al-Turk and S.J. Stohs. American Society of Pharmacology and Experimental Therapeutics, 1981, Atlanta, Georgia.

58. The Estriol Antagonistic Effect on Cellular Growth as Monitored by Ornithine Decarboxylase in the 17ß-Estradiol-Induced Immature Rat Uterus. L.A. Lavia, H.M. Lemon and S.J. Stohs. American Association of Cancer Research, 1981, Washington, D.C.

59. Altered Drug and Glutathione Metabolism in Diabetic Animals. S.J. Stohs, Symposium on Diabetes Research, 1982, the University of Nebraska Medical Center, Omaha, Nebraska.

60. Characterization of P5N Deficient Red Cells. M.S. Swanson, C.R. Angle, S.J. Stohs, J.M. Salhany and S. Wu. American Society of Pharmacology and Experimental Therapeutics, 1982, New Orleans, Louisiana.

61. Partial Purification of Human Pyrimidine-5'-Nucleotidase. C.R. Angle, R.S. Markin, and S.J. Stohs. Federation of American Societies of Experimental Biology, 1982, New Orleans, Louisiana.

62. Evidence for Zinc in the Active Site of Pyrimidine-5'-Nucleotidase. R.S. Markin, M.S. Swanson, C.R. Angle and S.J. Stohs. Federation of American Societies of Experimental Biology, 1982, New Orleans, Louisiana.

63. Further Characterization of Pyrimidine-5'-Nucleotidase Deficient Red Cells. M.S. Swanson, C.R. Angle and S.J. Stohs. American Pediatric Society, 1982, Washington, D.C.

64. Red Cell Cytidine Phosphates: A Stable Index of Lead Exposure Unaffected by Chelation. C.R. Angle, M.S. Swanson, M.S. McIntire and S.J. Stohs. American Pediatric Society, 1982, Washington, D.C.

65. Red Cell Cytidine Phosphates as a Stable Index of Lead Exposure. C.R. Angle, M.S. Swanson, M.S. McIntire and S.J. Stohs. International Congress of Clinical Toxicology, 1982, Snowmass, Colorado.

66. 7-Ethoxycoumarin O-Deethylation and Conjugation of 7-Hydroxycoumarin in Perfused Livers of Hypophysectomized Rats. W.A. Al-Turk, L.A. Reinke and S.J. Stohs. American Society of Pharmacology and Experimental Therapeutics and the Society of Toxicology, 1982, Louisville, Kentucky.

67. Percutaneous Absorption of Iodochlorhydroxyquin in Humans. F.W. Ezzedeen, S.J. Stohs, A.K. Anderson and J.M. Baldwin. Academy of Pharmaceutical Sciences, 1983, New Orleans, Louisiana.

68. Lipid Peroxidation and TCDD Toxicity. S.J. Stohs, M.Q. Hassan and W.J. Murray. Federation of American Societies of Experimental Biology, 1983, Chicago, Illinois.

69. Erythrocyte Nucleotides in Pyrimidine-5'-Nucleotidase Deficiency. M.S. Swanson, C.R. Angle, S.J. Stohs and R.S. Markin. Federation of American Societies of Experimental Biology, 1983, Chicago, Illinois.

70. Metabolism of Beta Keto Nitrosamines by Cytochrome P-450 and Prostaglandin Endoperoxide Synthetase Dependent Microsomal Preparations. D. Nagel, A.S. Helgeson, S.J. Stohs, S.M. Cohen, C. Raha and T. Lawson. American Association Cancer Research, 1983, San Diego, California.

71. Erythrocyte Pyrimidine Nucleotides in Uremia. Accumulation Independent of Pyrimidine-5'-Nucleotidase or Blood Lead. C.R. Angle, M.S. Swanson and S.J. Stohs. Sixth International Symposium on Pediatric Nephrology, 1983, Hannover, West Germany.

72. Protection Against TCDD-Induced Lipid Peroxidation by BHA, d-α-Tocopherol and Retinol Acetate. S.J. Stohs, M.Q. Hassan and W.J. Murray. International Symposium for the Study of Xenobiotics, 1983, West Palm Beach, Florida..B. Roch. American Society for Pharmacology and Experimental Therapeutics, 1980, Rochester, Minnesota.

73. New Aspects of Dilantin Therapy: Anti-Estrogenic and Anti-Mammary Carcinogenic Activity. H.M. Lemon, R. Pfeiffer, J. Campbell and S.J. Stohs. Omaha Mid-West Clinical Society, 1983, Omaha, Nebraska.

74. Changes in Glutathione and Glutathione Metabolizing Enzymes in Mouse and Human Erythrocytes and Lymphocytes as a Function of Age of Donor. S.J. Stohs, T. Lawson and F.H. El-Rashidy. Federation of American Societies of Experimental Biology, 1984, St. Louis, Missouri.

75. Possible Roles of Lipid Peroxidation and Glutathione Peroxidase in TCDD Toxicity. S.J. Stohs, M.Q. Hassan and W.J. Murray. Banbury Center Conference on Biological Mechanisms of Dioxin Action, 1984, Cold Spring Harbor, New York.

76. Anti-Mammary Carcinogenic Activity of Phenytoin. H.M. Lemon, S.J. Stohs, R. Pfeifer and J. Campbell. American Association Cancer Research, 1984, Toronto, Canada.

77. Dietary Selenium and TCDD Toxicity. S.J. Stohs, M.Q. Hassan and W.J. Murray. 6th International Symposium on Microsomes and Drug Oxidations, 1984, Brighton, England.

78. TCDD-Induced Lipid Peroxidation in Hepatic and extrahepatic Tissues. S.J. Stohs, M.Q. Hassan, Z.F. Al-Bayati, S.J. Hermansky and W.J. Murray. 9th International Congress of Pharmacology, 1984, London, England.

79. Deoxypyrimidine-5'-Nucleotidase Activity in Erythrocytes from A Pyrimidine 5'-Nucleotidase Deficient Subject. S.J. Stohs, C.R. Angle, L.R. Cook and M.A. Mitchell. 9th International Congress of Pharmacology, 1984, London, England.

80. Percutaneous Absorption of Clioquinol (Iodochlorhydroxyquin) in Dogs. S.J. Stohs and F.W. Ezzedeen. 9th International Congress of Pharmacology, 1984, London, England.

81. Pyrimidine-5'-Nucleotidase Isoenzyme Characterization in Lead Exposure. C.R. Angle, S.J. Stohs, L.R. Cook and M.A. Mitchell. Society of Toxicology, 1985, San Diego, California.

82. Hydrogen Peroxide and Free Radicals in TCDD Induced Microsomal and Mitochondrial Malondialdehyde Formation. S.J. Stohs, M.Q. Hassan, Z.A.F. Al-Bayati and W.J. Murray. Society of Toxicology, 1985, San Diego, California.

83. Assay of Human Erythrocyte Pyrimidine and Deoxypyrimidine 5'-Nucleotidase by Reversed Phase Isocratic High Performance Liquid Chromatography (HPLC). L.R. Cook, M.A. Mitchell, C.R. Angle and S.J. Stohs. Society of Toxicology, 1985, San Diego, California.

84. Glutathione, DNA Damage and Aging. S.J. Stohs. Free Radicals, Pathology and Aging Workshop, 1985, San Diego, California.

85. The Roles of Glutathione Peroxidase and Hydrogen Peroxide in TCDD-Induced Lipid Peroxidation. S.J. Stohs, Z.A.F. Al-Bayati, W.J. Murray and H.M. Pour. Biological Reactive Intermediates III, 1985, Baltimore, Maryland.

86. Glutathione Metabolism, DNA Damage, Antioxidants and Aging in Mice. S.J. Stohs, T. Lawson and L. Anderson. International Congress of Biomedical Gerontology, 1985, New York, New York.

87. TCDD, Lipid Peroxidation and Calcium. Z.A.F. Al-Bayati, S.J. Stohs, W.J. Murray and M.C. Pankaskie. American Society of Pharmacology and Experimental Therapeutics, 1985, Boston, Massachusetts.

88. Erythrocyte Arginase and the Isozymes of Pyrimidine-5'-nucleotidase as Correlates of Lead Exposure. C.R. Angle, S.J. Stohs, L.R. Cook and C. Kubitschek. AACT/AAPCC/ABMT/CAPCC Annual Meeting, 1985, Kansas City, Missouri.

89. TCDD, Dietary Iron and Iron Distribution in Female Rats. Z.A. Al-Bayati, S.J. Stohs and W.A. Al-Turk. Society of Toxicology, 1986, New Orleans, Louisiana.

90. Biochemical and Toxicological Effects of TCDD Congeners in Female Rats. M. A. Shara and S.J. Stohs. Society of Toxicology, 1986, New Orleans, Louisiana.

91. RBC Arginase, P5N and dP5N as Correlates of Blood Lead. C.R. Angle, L.R. Cook and S.J. Stohs. AAPCC/AACT/ABMT/CAPCC Annual Meeting, 1986, Sante Fe, New Mexico.

92. The Role of Glutathione and Its Metabolism in Aging. S.J. Stohs and T. Lawson. The Third Tokyo Symposium on Liver and Aging, 1986, Tokyo, Japan.

93. Glutathione, Free Radicals, Antioxidants and Aging. S.J. Stohs. Symposium on Frontiers in Hepatic Gerontology, 1986, Tokyo, Japan.

94. Effect of Thyroidectomy on 2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD) Induced Lipid Peroxidation. S.J. Hermansky, S.J. Stohs and H.A. Mohammadpour. Society of Toxicology, 1987, Washington, D.C.

95. Dietary Iron, and TCDD-Induced Alterations in Hepatic Lipid Peroxidation and Glutathione Content in Rats. M.A. Shara, W.A. Al-Turk, H.A.

Mohammadpour and S.J. Stohs. Society of Toxicology, 1987, Washington, D.C.

96. Effect of TCDD on the Hepatic and Testicular Distribution of Iron, Zinc and Copper in Rats. Z.Z. Wahba, Z.A.F. Al-Bayati and S.J. Stohs. Society of Toxicology, 1987, Washington, D.C.

97. Erythrocyte Membrane Fluidity as Related to Blood Lead. C.R. Angle, L.R. Cook, S.J. Stohs and R.C. Maxell. Society of Toxicology, 1987, Washington, D.C.

98. Effect of Feeding Antioxidants and Cabbage on DNA Damage, Glutathione Metabolism and Lipid Peroxidation in Aging Mice. S.J. Stohs and T.A. Lawson. American Society of Pharmacology and Experimental Therapeutics, 1987, Washington, D.C.

99. Induction of Hepatic DNA Single Strand Breaks in Rats by 2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD). S.J. Stohs, Z.Z. Wahba and T.A. Lawson. International Society for the Study of Xenobiotics, 1987, Clearwater, Florida.

100. 2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD) Induced Alterations in Lipid Peroxidation, Enzymes and Divalent Cations in Rat Testis. Z.A.F. Al-Bayati, Z.Z. Wahba and S.J. Stohs. International Society for the Study of Xenobiotics, 1987, Clearwater, Florida.

101. Factors Influencing The Induction of DNA Single Strand Breaks in Rats by 2,3,7,8-Tetrachlorodibenzo-p-dioxin. Z.Z. Wahba, S.J. Stohs, T.A. Lawson and W.J. Murray. Society of Toxicology, 1988, Dallas, Texas.

102. 2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD)-Induced Lipid Peroxidation in Responsive and Non-Responsive Mice. S.J. Stohs and H. Mohammadpour. Society of Toxicology, 1988, Dallas, Texas.

103. Decreases in Hepatic Glucocorticoid (GCR) and Epidermal Growth Factor (EGF) Receptor Binding in Mouse Liver After Treatment with 2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD). F.S. Lin, S.J. Stohs, L.S. Birnbaum, G.W. Lucier and J.A. Goldstein. American Society of Pharmacology and Experimental Therapeutics, 1988, Las Vegas, Nevada.

104. Biochemical Effects of TCDD in Skin and Liver of HRS/J Mice. S.J. Stohs, B.D. Abbott, F.S. Lin and L.S. Birnbaum. Society of Toxicology, 1989, Atlanta, Georgia.

105. TCDD-Induced Decreases in Rat Liver Membrane Fluidity. N. Alsharif, C.J. Grandjean and S.J. Stohs. Society of Toxicology, 1989. Atlanta, Georgia.

106. Dose and Time Dependent Effects of the Hepatotoxin Microcystin-LR in Mice. S.J. Hermansky, R.S. Markin and S.J. Stohs. Society of Toxicology, 1989. Atlanta, Georgia.

107. Effects of 2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD) on Hepatic Protein Bound (PB) and Non-Protein (NPB) Sulfhydryl (-SH) Groups in Female Rats. M.A. Shara and S.J. Stohs. Society of Toxicology, 1989. Atlanta, Georgia.

108. Role of the Ah Locus in the Regulation of the Effects of 2,3,7,8-Tetrachlorodibenzo-p-dioxin (RM) on Epidermal Growth Factor (EGFR), Glucocorticoid (GCR) and Estrogen (ER) Receptors in Mouse Liver. F.H. Lin, S.J. Stohs, L.S. Birmbaum, G. Clark, G. Lucier and J.A. Goldstein. Society of Toxicology, 1989. Atlanta, Georgia.

109. 2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD) Induced Hepatic DNA Single Strand Breaks (SSD) in Rats. Z.Z. Wahba, T.A. Lawson, W.J. Murray and S.J. Stohs. American Society of Pharmacology and Experimental Therapeutics, 1989. New Orleans, Louisiana.

110. Evidence for the Induction of an Oxidative Stress by 2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD). S.J. Stohs, N.A. Alsharif, M. Shara and Z.Z. Wahba. 4th International Symposium on Biological Reactive Intermediates, 1990. Tucson, Arizona.

111. TCDD-Induced Production of Superoxide Anion and DNA Single Strand Breaks in Peritoneal Macrophage of Rats. N.Z. Alsharif, T. Lawson and S.J. Stohs. Society of Toxicology, 1990. Miami, Florida.

112. Evaluation of Potential Chemoprotectants and Antidotes Against Microcystin-LR Hepatotoxicity. S.J. Stohs and S.J. Hermansky. Society of Toxicology, 1990. Miami, Florida.

113. Hepatic Lipid Peroxidation, Sulfhydryl Status and Toxicity of the Blue-Green Algal Toxin Microcystin-LR in Mice. S.J. Hermansky, S.J. Stohs, W.J. Murray and R.S. Markin. Society of Toxicology, 1990. Miami, Florida.

114. The Ah Locus Mediates the Effects of 2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD) on the Epidermal Growth Factor Receptor (EGFR) Through a Mechanism Which Does Not Involve EGFR mRNA. F.H. Lin, G. Clark, S.J. Stohs, L.S. Birnbaum, G. Lucier and J.A. Goldstein. Society of Toxicology, 1990. Miami, Florida.

115. Oxidative Stress in the Toxicity of 2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD). S.J. Stohs, M.A. Shara, N.Z. Alsharif, Z.Z. Wahba and Z.A.F. Al-Bayati. 10th International Conference on Organohalogen Compounds, 1990. Bayreuth, Federal Republic of Germany.

116. Excretion of Lipid Metabolites in the Urine of Rats in Response to Oxidative Stress. S.J. Stohs and M.A. Shara. International Society for Free Radical Research, 1990. Pasadena, California.

117. Oxidative Stress Induced by TCDD is Mediated by the Ah-Receptor Complex. N.Z. Alsharif and S.J. Stohs. International Society for Free Radical Research, 1990. Pasadena, California.

118. Dimethylthiourea (DMTU) Reduces Proteinuria in Adriamycin Nephrosis (AN), Possibly by Stimulating Renal Glutathione Metabolism. L.S. Milner, M.T. Houser and S.J. Stohs. American Society of Nephrology, 1990. Washington, D.C.

119. Glutathione Ester (GE) Moderates Mercuric Chloride (MC)-Induced Acute Renal Failure (ARF). M.T. Houser, L.S. Milner, P.C. Kolbeck, S.H. Wei and S.J. Stohs. American Society of Nephrology, 1990. Washington, D.C.

120. Oxidative Stress Induced by TCDD is Mediated by the Ah-Receptor Complex. N.Z. Alsharif and S.J. Stohs. Society of Toxicology, 1991. Dallas, Texas.

121. Ricin-Induced Oxidative Stress in Mice. D.F. Muldoon and S.J. Stohs. Society of Toxicology, 1991. Dallas, Texas.

122. Effect of 2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD) on Hepatic Protein Bound (PB) and Non-protein Bound (NPB) Sulfhydryl (-SH) Groups, and Reduced Pyridine Nucleotides in Female Rats. M.A. Shara and S.J. Stohs. Society of Toxicology, 1991. Dallas, Texas.

123. Excretion of Formaldehyde, Acetaldehyde, Malondialdehyde and Acetone in the Urine of TCDD-Treated Rats. M.A. Shara and S.J. Stohs. Society of Toxicology, 1991. Dallas, Texas.

124. In Vitro Induction of Reactive Oxygen Species by 2,3,7,8-Tetrachlorodibenzo-p-dioxin and Other Polyhalogenated Cyclic Hydrocarbons in Peritoneal Macrophages, and Heaptic Mitochondria and Microsomes. M. Bagchi and S.J. Stohs. 11th International Symposium on Chlorinated Dioxins and Related Compounds, 1991. Research Triangle Park, North Carolina.

125. The In Vivo Activation of Rat Peritoneal Macrophages by 2,3,7,8-Tetrachlorodibenzo-p-dioxin. N.Z. Alsharif and S.J. Stohs. 11th International Symposium on Chlorinated Dioxins and Related Compounds, 1991. Research Triangle Park, North Carolina.

126. Glutathione Monoethyl Ester (GMEE) Treatment Post-exposure Moderates Mercuric Chloride (MC)-induced Acute Renal Failure (ARF). M.T. Houser, L.S. Milner, P.C. Kolbeck and S.J. Stohs. International Symposium on Acute Renal Failure, 1991. Chapel Hill, North Carolina.

127. Modulation of Ricin Toxicity in Mice. D.F. Muldoon and S.J. Stohs. Society of Toxicology, 1992. Seattle, Washington.

128. Endrin-Induced Oxidative Stress in Female Sprague-Dawley Rats. M. Bagchi, E.A. Hassoun, D. Bagchi and S.J. Stohs. Society of Toxicology, 1992. Seattle, Washington.

129. Excretion of Acetaldehyde, Formaldehyde, Acetone and Malondialdehyde in Urine of Rats Following an Acute Dose of Ethanol. J. Moser, D. Bagchi and S.J. Stohs. Society of Toxicology, 1992. Seattle, Washington.

130. The Effects of Anti-TNF-α Monoclonal Antibody and Dexamethasone on TCDD-Induced Oxidative Stress in Mice. N.Z. Alsharif, E. Hassoun, M. Bagchi and S.J. Stohs. Society of Toxicology, 1992. Seattle, Washington.

131. Excretion of Malondialdehyde, Acetaldehyde and Acetone in the Urine of Rats in Response to an Acute Dose of Malondialdehyde. P.I. Akubue and S.J. Stohs. Society of Toxicology, 1992. Seattle, Washington.

132. Curriculum Development at Creighton University. B.W. Shinn, J.E. Fincham and S.J. Stohs. American Association of Colleges of Pharmacy, 1992. Washington, D.C.

133. Age-Related Changes in Lipid Peroxidation in Isolated Rod Outersegments of Rat Retina. S.E. Ohia, M. Bagchi and S.J. Stohs. Society of Neuroscience, 1992. Anaheim, California.

134. Effect of Age on Lipid Peroxidation in Isolated Rod Outersegments of Rat Retina. M. Bagchi, S.E. Ohia and S.J. Stohs. Symposium on Molecular Mechanisms of Aging, 1992. Kansas City, Missouri.

135. In vitro and in vivo induction of oxidative stress by smokeless tobacco extract (STE). S.J. Stohs, M. Bagchi, D. Bagchi and E.A. Hassoun. Society of Toxicology, 1993. New Orleans, Louisiana.

136. Comparative effects of endrin on the hepatic lipid peroxidation, DNA damage, and nitric oxide production by peritoneal lavage cells from C57BL/6J and DBA/2 mice. M. Bagchi, E.A. Hassoun, P. Akubue and S.J. Stohs. Society of Toxicology, 1993. New Orleans, Louisiana.

137. Protective effects of antioxidants against endrin-induced hepatic lipid peroxidation, DNA damage, and excretion of urinary lipid metabolites. D. Bagchi, E.A. Hassoun, M. Bagchi and S.J. Stohs. Society of Toxicology, 1993. New Orleans, Louisiana.

138. Excretion of lipid metabolites in the urine of ricin-treated mice. D.F. Muldoon, D. Bagchi and S.J. Stohs. Society of Toxicology, 1993. New Orleans, Louisiana.

139. Assessment of potential glycosidase inhibitors, AZT and DDC as chemoprotectants against ricin toxicity in vitro. E.A. Hassoun, D. Bagchi, V.F. Roche and S.J. Stohs. Society of Toxicology, 1993. New Orleans, Louisiana.

140. Activity of glycosidase inhibitors against ricin toxicity in cell cultures. K.A. Mereish, D. Bagchi and S.J. Stohs. Society of Toxicology, 1993. New Orleans, Louisiana.

141. Development of oxidative stress by chlorpyrifos and Fenthion. G. Mukherjee, N. Maulik, G. Cordis, M. Bagchi, D. Bagchi, S.J. Stohs and D.K. Das. International Symposium on Oxygen Radicals and Antioxidants in Biotechnology and Medicine, 1993. Calcutta, India.

142. Protective effects of free radical scavengers against smokeless tobacco extract (STE) induced oxidative stress. D. Bagchi, M. Bagchi and S.J. Stohs. International Symposium on Oxygen Radicals and Antioxidants in Biotechnology and Medicine, 1993. Calcutta, India.

143. Endrin induced changes in lipid peroxidation and regional distribution of catalase activity in rat brain. M. Bagchi, D. Bagchi, S. Ghosh and S.J. Stohs. International Symposium on Oxygen Radicals and Antioxidants in Biotechnology and Medicine, 1993. Calcutta, India.

144. Modulation of ricin toxicity by tumor necrosis factor alpha antibody. D.F. Muldoon, D. Bagchi and S.J. Stohs. Society of Toxicology, 1994. Dallas, Texas.

145. Induction of stress protein, DNA single strand breaks and lipid peroxidation in endrin-treated rats, and protection by antioxidants. S.J. Stohs, D. Bagchi, M. Bagchi, S. Kumar and E. Hassoun. Society of Toxicology, 1994. Dallas, Texas.

146. Effect of vitamin E succinate on smokeless tobacco extract (STE)-induced production of nitric oxide by rat peritoneal macrophages and the J774A.1 macrophage cell line. E. Hassoun, D. Bagchi, M. Bagchi and S.J. Stohs. Society of Toxicology, 1994. Dallas, Texas.

147. Protective effects of lazaroids on the endrin-induced changes in lipid peroxidation, DNA damage and regional distribution of catalase activity in rat brain. M. Bagchi, S. Ghosh, D. Bagchi, E. Hassoun and S.J. Stohs. Society of Toxicology, 1994. Dallas, Texas.

148. Chromium-induced excretion of urinary lipid metabolites and production of reactive oxygen species by peritoneal macrophages and hepatic subcellular fractions in Sprague-Dawley rats. D. Bagchi and S.J. Stohs. Society of Toxicology, 1994. Dallas, Texas.

149. Age-related changes in lipid peroxidation, glutathione, and catalase and superoxide dismutase activities in brain, liver, lung and heart tissues of Fisher 344 rats. D. Bagchi, M. Bagchi, S.E. Ohia and S.J. Stohs. Molecular Mechanism of Aging Conference, 1994. Kansas City, Missouri.

150. Potentiation of adrenergic neurosecretion in mammalian iris-ciliary body by hydrogen peroxide. S. Ohia, M. Bagchi and S. Stohs. International Society for Eye Research, 1994. Miami, Florida.

151. Age-related changes in the regulation of norepinephrine release in human iris ciliary body by hydrogen peroxide. M. Bagchi, D. Bagchi, S.E. Ohia and S.J. Stohs. Society for Neuroscience, 1994. Miami Beach, Florida.

152. Potentiation of Adrenergic Neurosecretion in Mammalian Iris-Ciliary Body by Hydrogen Peroxide. M. Bagchi, S.E. Ohia and S.J. Stohs. International Society for Eye Research, 1994. Delhi, India.

153. In vivo induction of differential heat shock gene expression in liver, brain, lung and heart by selected pesticides. D. Bagchi and S.J. Stohs. Indian Science Congress, 1995. Calcutta, India.

154. Induction of free radicals and HSP90 in gastric cells by Helicobacter pylori and antioxidant protection. D. Bagchi, G. Battacharya and S.J. Stohs. Society of Toxicology, 1995. Baltimore, Maryland.

155. Ricin-induced lipid peroxidation in microsomes and mitochondria. D.F. Muldoon and S.J. Stohs. Society of Toxicology, 1995. Baltimore, Maryland.

156. Comparative teratological studies on TCDD, endrin and lindane in C57BL/6J and DBA/2J mice. E. Hassoun and S.J. Stohs. Society of Toxicology, 1995. Baltimore, Maryland.

157. Heat shock protein (Hsp) gene expression by selected pesticides. S.J. Stohs and D.Bagchi. Society of Toxicology, 1995. Baltimore, Maryland.

158. Age-related changes in stress proteins, lipid peroxidations and antioxidant defense in Fisher 344 rats. M. Bagchi, D. Bagchi, G. Battacharya, S.E. Ohia and S.J. Stohs. Society of Toxicology, 1995. Baltimore, Maryland.

159. Adapting pharmaceutical education to meet the changing needs of pharmacy practice. S.J. Stohs. Federation International Pharmaceutique, 1995. Stockholm, Sweden.

160. Age-related changes in lipid peroxidation and antioxidant defense in Fischer 344 rats. M. Bagchi, D. Bagchi, E.B. Patterson, L. Tang and S.J. Stohs. Symposium on Myocardial Preservation and Cellular Adaptation, World

Congress on International Society of Adaptive Medicine, 1995. Madras, India.

161. Implication of DNA damage during reperfusion of ischemic myocardium: Identification of DNA-OH adduct. G.A. Cordis, D. Bagchi, W. Riedel, S.J. Stohs and D.K. Das. Symposium on Myocardial Preservation and Cellular Adaptation, World Congress on International Society of Adaptive Medicine, 1995. Madras, India.

162. TCDD, endrin and lindane induced increases in lipid metabolites in maternal sera and amniotic fluids of pregnant C57BL/6J and DBA/2J mice. E.A. Hassoun, D. Bagchi and S.J. Stohs. Society of Toxicology, 1996. Anaheim, CA.

163. In vitro free radical production in human keratinocytes induced by smokeless tobacco extract (STE). M. Bagchi, C. Kuzynski, E.A. Patterson, L. Tang, D. Bagchi and S.J. Stohs. Society of Toxicology, 1996. Anaheim, CA.

164. Cadmium and chromium induced oxidative stress and programmed cell death in cultured J774A.1 macrophage cells. M.X. Tran, S.J. Stohs, S. Newton, D. Bagchi, M. Bagchi, L. Tang and S.D. Ray. Society of Toxicology, 1996. Anaheim, CA.

165. Comparative in vitro and in vivo protein kinase C activation by selected pesticides and transition metal salts. S.J. Stohs, D. Bagchi, M. Bagchi and L. Tang. Society of Toxicology, 1996. Anaheim, CA.

166. Effects of vitamin E succinate (VES) on naphthalene-induced hepatic and brain lipid peroxidation, DNA single strand breaks, glutathione depletion, membrane microviscosity and excretion of urinary lipid metabolites in rats. D. Bagchi, P.J. Vuchetich, M. Bagchi, E.A. Hassoun, L. Tang and S.J. Stohs. Society of Toxicology, 1996. Anaheim, CA.

167. Effects of chronic administration of sodium dichromate [Cr(VI)] and cadmium chloride [Cd(II)] to rats on the excretion of urinary lipid metabolites and production of mitochondrial and microsomal lipid peroxidation. P.J. Vuchetich, D. Bagchi, M. Bagchi, M. Tran and S.J. Stohs. Society of Toxicology, 1996. Anaheim, CA.

168. Protective effects of zinc salts on TPA-induced hepatic and brain lipid peroxidation, glutathione depletion, DNA fragmentation, and peritoneal macrophage activation in female Swiss-Webster mice. D. Bagchi, P.J. Vuchetich, M. Bagchi, M. Tran, L. Tang, R. Krohn and S.J. Stohs. American Society of Pharmacology and Experimental Therapeutics, 1996. Washington, DC.

169. Oxidative stress and programmed cell death of cultured J774A.1 macrophage cells in association with cadmium and chromium ions. D. Bagchi, M.X. Tran,

S.J. Stohs, S. Newton, M. Bagchi, L. Tang and S.D. Ray. Conference on Advances in Toxicology and Applications to Risk Assessment, 1996. Dayton, OH.

170. Comparative in vitro and in vivo free radical scavenging abilities of selected zinc salts and antioxidants. D. Bagchi, P. Vuchetich, M. Bagchi, R.P. Scheckenbach and S.J. Stohs. Annual Meeting of the American College of Nutrition, 1996. San Francisco, CA.

171. Age-related changes in lipid peroxidation and antioxidant defense in Fischer 344 rats. M. Bagchi, D. Bagchi, E.B. Patterson, L. Tang and S.J. Stohs. American Aging Association Annual Meeting, 1996. San Francisco, CA.

172. Protection against chemically-induced oxidative gastrointestinal tissue injury in rats by bismuth salts. D. Bagchi, O.R. Carryl, P.J. Vuchetich, M. Bagchi, L. Tang, M.X. Tran and S.J. Stohs. American College of Gastroenterology Annual Meeting, 1996. Washington, DC.

173. Naphthalene-induced oxidative stress and DNA damage in cultured macrophage J774A.1 cells. S.J. Stohs, M. Bagchi, J. Balmori and D. Bagchi. Society of Toxicology, 1997. Cincinnati, OH.

174. Cadmium and chromium induced oxidative stress and apoptotic cell death in cultured human chronic myelogenous leukemic K562 cells. D. Bagchi, S.S. Joshi, C. Kuszynski, M. Bagchi and S.J. Stohs. Society of toxicology, 1997. Cincinnati, OH.
175. Helicobacter pylori-induced oxidative stress in DNA damage in normal human gastric cells. B. Buchanan, D. Bagchi, T.R. McGinn, M. Bagchi and S.J. Stohs. Society of Toxicology, 1997. Cincinnati, OH.

176. Effect of smokeless tobacco extract (STE) on DNA cell cycle analysis, apoptosis and lipid peroxidation in human oral keratinocytes. M. Bagchi, C. Kuszynski, D. Bagchi, P.T. Saini and S.J. Stohs. Society of Toxicology, 1997. Cincinnati, OH.

177. Creighton University's Non-traditional Doctor of Pharmacy degree offering. K.R. Keefner and S.J. Stohs. American Association of Colleges of Pharmacy, 1997. Washington, DC.

178. Protection against chemically-induced oxidative injury in human gastric mucosal cells by bismuth subsalicylate (BSS). D. Bagchi, O.R. Carryl, M.X. Tran, R.L. Krohn, M. Bagchi, A. Garg, D.J. Bagchi and S.J. Stohs. Annual Meeting of the American College of Gastroenterology, 1997. Chicago, IL.

179. Clinical doctoral programs in physical therapy and occupational therapy. S.J. Stohs, A.J. Threlkeld and C. Peyton. World Congress on Allied Health, 1997. Telford, England.

180. Modulation of intracellular oxidized states in cultured J774A.1 macrophage cells and neuroactive PC-12 cells by a grape seed proanthocyanidin extract. D. Bagchi, M. Bagchi, J. Balmoori, C.A. Kuszynski and S.J. Stohs. Annual Meeting of the American College of Nutrition, 1997. New York, NY.

181. Protective role of Clarithromycin against Helicobacter pylori-induced oxidative stress and DNA damage in human gastric cells. T.R. McGinn, B. Buchanan, D. Bagchi, M. Hutzler and S.J. Stohs. Annual Meeting of the American College of Gastroenterology, 1997. Chicago, IL.

182. Protective effects of vitamins C and E, and a grape seed proanthocyanidin extract (GSPE) on smokeless tobacco-induced oxidative stress and apoptotic cell death in human oral keratinocytes. M. Bagchi, J. Balmoori, D. Bagchi, C. Kuszynski and S.J. Stohs. Annual Meeting of the Oxygen Society, 1997. San Francisco, CA.

183. Comparative in vitro and in vivo free radical scavenging abilities of a novel grape seed proanthocyanidin extract and selected antioxidants. S.J. Stohs, R.P. Scheckenbach, R.L. Krohn, J. Balmoori, M. Bagchi, C.A. Kuszynski, A. Garg and D. Bagchi. International Symposium on Stress Adaptation, Prophylaxis and Treatment, 1998. Calcutta, India.

184. Acute and chronic stress-induced oxidative gastrointestinal mucosal injury in rats, and protection by bismuth subsalicylate (BSS). D. Bagchi, C.B. Williams, M. Milnes, R.L. Krohn, M. Bagchi, J. Balmoori, X. Ye, M.X. Tran, S.J. Stohs, O.R. Carryl and S. Mitra. Digestive Disease Week, 1998. New Orleans, LA.

185. Mechanism of gastroprotection by bismuth subsalicylate against chemically-induced oxidative injury in human gastric mucosal cells. D. Bagchi, T.R. McGinn, X. Ye, J. Balmoori, M. Bagchi, S.J. Stohs, O.R. Carryl and S. Mitra. Digestive Disease Week, 1998. New Orleans, LA.

186. The cytotoxic effects of a novel grape seed proanthocyanidin extract on cultured human cancer cells. S.S. Joshi, X. Ye, W. Liu, M. Bagchi, H.G. Preuss, D. Bagchi and S.J. Stohs. American Association for Cancer Research, 1998. New Orleans, LA.

187. Cytotoxicity of a novel grape seed proanthocyanidin extract against selected human cancer cells. S.S. Joshi, X. Ye, W. Liu, M. Bagchi, H.G. Preuss, D. Bagchi and S.J. Stohs. Second International Conference on Natural Antioxidants and Anticarcinogens in Nutrition, Health and Disease, 1998. Helsinki, Finland.

188. In vitro and in vivo free radical scavenging abilities of a grape seed proanthocyanidin extract and selected antioxidants. D. Bagchi, R.L. Krohn, J. Balmoori, M. Bagchi, C.A. Kuszynski, A. Garg and S.J. Stohs. Second

International Conference on Natural Antioxidants and Anticarcinogens in Nutrition, Health and Disease, 1998. Helsinki, Finland.

189. Smokeless tobacco-induced oxidative stress, DNA damage and apoptotic cell death in human oral keratinocytes, and protection by antioxidants. D. Bagchi, M. Bagchi, S.S. Joshi, J. Balmoori, C. Kuszynski and S.J. Stohs. The Gordon Conference, 1998. Newport, RI.

190. Acute and chronic stress-induced gastrointestinal injury in rats, protection by a novel grape seed proanthocyanidin extract (GSPE). M. Bagchi, C.B. Williams, M. Milnes, J. Balmoori, X. Ye, D. Bagchi and S.J. Stohs. Annual Meeting of the Oxygen Society, 1998. Washington, DC.

191. Role of oxidative stress in the chronic toxicity of TCDD in C57BL/6J female mice. N.Z. Alsharif, L. Tang, E. Hassoun, T. El Metwally, C. Pedersen, M. Shara, and S.J. Stohs. Society of Toxicology, 1999. New Orleans, LA.

192. Role of p53 tumor suppressor gene in the toxicity of TCDD, endrin, naphthalene and chromium (VI) in the liver and brain tissues of mice. D. Bagchi, J. Balmoori, M. Bagchi, X. Ye, C.B. Williams, and S.J. Stohs. Society of Toxicology, 1999. New Orleans, LA

193. Smokeless Tobacco Induced Modulation of p53 Gene and Protective Effect of Antioxidants. M. Bagchi, S.S. Joshi, D. Bagchi, X. Ye, and S.J. Stohs. Society of Toxicology, 1999. New Orleans, LA.

194. Free Radicals and Grape Seed Proanthocyanidin Extract: Importance in Human Health and Disease. D. Bagchi, M. Bagchi, and S.J. Stohs. Conference on Emerging Potentials of Antioxidant Therapy, 1999. Goa, India.

195. Effective Integration of Laptop Computers in Classroom and Clerkship Sites and Creighton University. S.E. Ohia, G. G. Glynn, M. C. Makoid, M.S. Monaghan, and S.J. Stohs. A.A.C.P. Annual Meeting, 2000. San Diego, CA.

196. Protective effects of vitamins C and E and a novel grapeseed proanthocynadin extract on smokeless tobacco induced oxidative stress and modulation of Bcl-2, p53 and c-myc genes. M. Bagchi, S.S. Joshi, D. Bagchi, X. Ye, and S.J. Stohs. SFRR Europe Winter Meeting, 1999. Dinard, France.

197. Role of p53 tumor suppressor gene in chromium (VI)-induced oxidative stress and DNA damage. D.Bagchi, M. Bagchi, and S.J. Stohs. Conference on Molecular Mechanisms of Metal Toxicity and Carcinogenesis, National Institute of Occupational Safety and Health, 2000. Morgantown, WV.

198. Comparative toxicological evaluation of chromium polynicotinate and chromium picolinate. M. Bagchi, P. Lim, S.J. Stohs, H. Preuss and D. Bagchi. Society of Toxicology, 2001. San Francisco, CA.

199. Beneficial Effects of a Novel Niacin Bound Chromium in Athletes and Hypercholesterolemic Patients. M. Bagchi, H. Preuss, P. Lim, S.J. Stohs and D. Bagchi. International Congress of Toxicology, 2001. Brisbane, Australia.

200. Entry-Level Professional Doctoral Programs in Physical Therapy and Occupational Therapy at Creighton University. S. J. Stohs, A. J. Threlkeld, and R. Padilla. World Congress III of Health Professions, 2001. San Juan, Puerto Rico.

201. Transitional (Post-Professional) Web-Based Clinical Doctoral Programs in Physical Therapy and Occupational Therapy at Creighton University. S. J. Stohs, G. Jensen, B. Coppard, A. J. Threlkeld, and R. Padilla. World Congress III of Health Professions, 2001. San Juan, Puerto Rico.

202. Grape seed proanthocyanidins as novel dietary antioxidants. D. Bagchi, H.G. Preuss, M. Bagchi and S.J. Stohs. European Society for Free Radical Research, 2001. Rome, Italy.

203. Oxidative stress and toxicity. S.J. Stohs. Central States Society of Toxicology, 2001. Kansas City, MO.

204. Who owns intellectual property associated with web-based courses? S.J. Stohs and G.D. Jahn. American Assocation of Colleges of Pharmacy Annual Meeting, 2001. Toronto, Canada.

205. Entry-level and a post-professional clinical doctoral programs in occupational therapy (OTD). S.J. Stohs, R. Padilla, B. Coppard, and C. Royeen. World Congress of Occupational Therapists, 2002. Stockholm, Sweden.

206. Antimicrobial effects of natural antioxidants on Helicobacter pylori. A. Chatterjee, D. Bagchi, T. Yasmin and S.J. Stohs. Infectious Diseases Society of American Annual Meeting, 2002. Chicago, IL.

207. Entry level and post-professional doctoral programs in physical therapy (DPT) and occupational therapy (OTD) at Creighton University. S.J. Stohs, R. Padilla, and R. Sandstrom. Association of Schools of Allied Health Professions, 2002. San Diego, CA.

208. A 90-day chronic toxicity study of a novel natural (-) – Hydroxycitric acid from *Garcinia cambogia*. S.E. Ohia, S.J. Stohs, M. Shara, T. Hossain, A. Chatterjee, M. Bagchi and D. Bagchi. Society of Toxicology, 2003. Salt Lake City, UT.

209. Invivo exposure to an ephedra containing metabolic nutrition system does not alter serum biochemistry and histopathology of seven vital target organs of

B6C3F1 mice. S. Stohs, S. Gross, C. Patel, R. Hackman and S. Ray. Society of Toxicology, 2003. Salt Lake City, UT.

210. Prior exposure of Helicobacter pylori to bile salts and sodium chloride increases susceptibility to clarithromycin. A. Chatterjee, T. Yasmin, A. Hossain, D. Bagchi and S. Stohs. American Society of Microbilogy, 2003. Washington, DC.

211. Mechanisms of cell death after acetaminophen overdose: Apoptosis or oncotic necrosis? S.D. Ray, S. Gross, A. Chou, C. Brucculeri, D. Bagchi and S. Stohs. Experimental Biology Annual Meeting, 2003, San Diego, CA.

212. Entry-level and post-professional clinical doctoral programs in physical therapy (DPT): an administrative perspective. S.J. Stohs, G.M. Jensen, C. Goulet and R.W. Sandstrom. World Conference on Physical Therapy, 2003. Barcelona, Spain.

213. The effects of hydroxycitric acid extract and fluoxetine on rat brain cortex neurotransmitters after 30, 60 and 90 days treatment. M. Shara., S.J. Stohs, D. Bagchi, M. Bagchi and S. Ohia. Society of Toxicology, 2004. Baltimore, MD.

214. Exposure for one year to a metabolic nutrition system containing ephedra and caffeine does not alter serum chemistry profile or target organ histopathology of B6 C3 F1 mice. S.D. Ray, S. Stohs and R. Hackman. Society of Toxicology, 2004. Baltimore, MD.

215. Safety of a novel, natural extract of hydroxycitric acid, a supplement for weight management. D. Bagchi, M. Shara, S. E. Ohia, T. Yasmin, M. Bagchi, A. Chatterjee, and S.J. Stohs. Society of Toxicology, 2004. Baltimore, MD.

216. Citrus aurantium: Safe and effective in weight management? S.J. Stohs, D. Bagchi and H. Preuss. Society of Free Radicals Research, 2004. Tamil Nadu, India.

217. Citrus fruits in weight management: case studies – safety and efficacy of Citrus aurantium (bitter orange). S.J. Stohs and H.G. Preuss. WorldNutra 2004, San Francisco, CA.

218. Four-week exposure to a novel nutritional mixer containing a series of polyphenolic phytochemicals antagonizes acetaminophen-induced hepatotoxicity in vivo. S.J. Stohs, A.Nagori, A. Naqvi, N.Shah and S.D. Ray. Society of Toxicology, 2005. New Orleans, LA.

219. Activation of endonuclease or caspase-activated DNASE (CAD) as a marker of apoptosis rather than necrosis in drug- or chemical-induced oncosis in vivo. S.D. Ray, S. Stohs and G. B. Corcoran. Society of Toxicology, 2005. New Orleans, LA.

220. Development of web-based programs/pathways from an administrative perspective. S.J. Stohs. Symposium on the Virtual Frontier, 2005. Omaha, NE.

221. Selected nutrients in muscle atrophy and advancing age-related disorders. S.J. Stohs. WorldNutra 2005. Anaheim, CA.

222. Glycemic index: Impact on diabetes and metabolic syndrome. S.J. Stohs, WorldNutra 2006. Reno, NV.

223. In vivo exposure effects of a complex metabolic nutrition system on serum chemistry and histopathology: A one-year safety and efficacy study. S.D. Ray, J. Rathod, D. Zinkovsky, E.Bulku, S. Ismail, J. Gigliotti, R. Hackman and S. Stohs. American College of Nutrition, 2006. Reno, NV.

224. Long-term exposure effects of a novel phytochemical-nutraceutical mixture (metabolic nutrition system – platinum) on serum biochemistry and histopathology of seven vital target organs of B6 C3 F1 mice. S.D. Ray, S. Patel, J. Rathod, N. Patel, E. Bulku, D. Zinkovsky, R.M. Hackman and S.J. Stohs. Society of Toxicology, 2006. San Diego, CA.

225. Eight-week exposure effects of a novel dietary supplement – ThermoPlus on serum biochemistry and histopathology of vital target organs of fisher rats. S.D. Ray, M. Parmar, D. Zinkovsky, I. Syed, J. Rathod, K. Sajh, R.M. Hackman and S.J. Stohs. Society of Toxicology, 2007. Charlotte, NC.

226. Importance of proper hydration: A novel rehydration drink supported by research studies. S.J. Stohs, P. Snell, R. Ward and C. Kandaswami. Institute for Food Technology, 2007. Chicago, IL.

227. Dietary supplement ThermoPlus reduces the level of oxidative stress and stabilizes the genomic integrity in the liver and kidneys of fisher 334 rats. S.D. Ray, E. Bulko, M. Parmar, I. Syed, C. Patel, S. Bhatt, R.M. Hackman and S.J. Stohs. American College of Nutrition, 2007. Orlando, FL.

228. The AdvoCare experience in monitoring adverse events. S.J. Stohs and T. Dollar. American College of Nutrition, 2007. Orlando, FL.

229. Effects of an adaptogen-based supplement (A-Supreme) on stress parameters in healthy volunteers. M. Shara, S. J. Stohs and E. Kakish. American College of Nutrition, 2008. Arlington, VA.

230. Safety evaluation of Super CitriMax (HCA-SX), a natural extract of (-)-hydroxycitric acid derived from *Garcinia cambogia*. S. J. Stohs, S. E. Ohia, H. G. Preuss, M. Bagchi, F. C. Lau, and D. Bagchi. American College of Nutrition, 2009, Orlando, FL.

231. Are non-nutritive sweeteners as safe as sugar? S. J. Stohs. American College of Nutrition, 2009, Orlando, FL.

232. Efficacy and safety of Super CitriMax(HCA-SX), a novel weight loss supplement derived from *Garcinia cambogia*. International Society for Nutraceuticals and Functional Foods, 2009, San Francisco, CA

233. *p*-Synephrine safety study: A randomized clinical study. M. Shara and S. J. Stohs. American College of Nutrition, 2011, Morristown, NJ.

234. Nutritional supplements in the surgical patient. S. J. Stohs, S. J. Dudrick. American college of Nutrition, 2011, Morristown, NJ.

235. 60 Day human double blind, placebo-controlled safety study on Citrus aurantium (bitter orange) extract. S. J. Stohs, G. R. Kaats, H. Miller, H. G. Preuss. American College of Nutrition. 2012. Morristown, NJ.

236. Review of the safety and efficacy of banaba and bitter orange extracts. S. J. Stohs. International Society for Nutraceuticals and Functional Foods, 2012. Kona, Hawaii

237. Review of the safety and efficacy of banaba and bitter orange extracts. S. J. Stohs. International Society for Nutraceuticals and Functional Foods, 2012. Kona, Hawaii.

238. Nutraceuticals and Dietary Supplements in enhanced sports performance. S.J.Stohs. Institute of Food Technicians, 2014, New Orleans, LA

239. Role of Dietary Supplements in Disease Prevention and Management. S. J. Stohs, Fourth International Meeting of Pharmacy and Pharmaceutical Sciences, 2014, Istanbul, Turkey.

240. Major changes in clinical pharmacy education and practice. S.J.Stohs. Fourth International Meeting of Pharmacy and Pharmaceutical Sciences, 2014, Istanbul, Turkey.

241. The effects of supplementation with Advantra Z alone and in the combination with caffeine on lypolytic and cardiovascular responses during resistance exercise. N.A. Ratamess, J. A. Bush, W.J. Kraemer, S. J. Stohs, V. G. Nocera, M. D. Leise, K. B. diamond, L. Pigott, J. Pacifico, C. Noonan, A.D. Faigenbaum. International Society of Sports Nutrition. 2015. Austin, TX.

242. Effect of p-synephrine and caffeine supplementation on metabolic responses during heavy resistance exercise. J.A. bush, N>D. Ratamess, J. Kang, W.J. Kraemer, S.J. Stohs, V.G. Nocera, M.D. Leise, K.B. Diamond, L. Pigott, J. Pacifico, C. Noonan, A.D. Fagenbaum. National Strength and Conditioning Association. 2015. Orlando, FL.

COURSES DEVELOPED:

Pharmaceutical Biochemistry, 6 cr
Clinical Chemistry and Biochemistry, 2 cr
Chemotherapy and Immunotherapy, 4 cr
Immunologic Systems of Defense, 2 cr
Introduction to Nutrition and Diet Therapy, 2 cr
Basic Life Support for Pharmacists, 1 cr
Drug Metabolism and Disposition, 2 cr
Research Design and Biostatistics, 3 cr

TEACHING INTERESTS:

Clinical education and nutrition; toxicology; food and nutritional toxicology. chemotherapy; drug metabolism; clinical chemistry and biochemistry; biochemistry.

RESEARCH INTERESTS:

Clinical nutrition; extrahepatic drug metabolism; enzyme induction; xenobiotic metabolism in normal and disease states; drug toxicity as a function of age; glutathione metabolism; role of oxidative stress in xenobiotic toxicology; biochemistry of heavy metal toxicity; chemical carcinogenesis; dietary supplement safety and efficacy.

EDUCATIONAL AND SCIENTIFIC CONFERENCES ATTENDED:

American Society of Pharmacognosy (ASP)-Boulder, CO, 1960; Houston, TX, 1961; Chapel Hill, NC 1963; Minneapolis, MN 1966; Corvallis, OR, 1969; Columbus, OH, 1972; Jekyll Island, GA, 1973; Chicago, IL, 1974; Seattle, WA 1977.

Academy of Pharmaceutical Sciences - San Francisco, CA, 1971; Houston, TX, 1972; Chicago, IL, 1974; San Francisco, CA, 1975; Montreal, Canada, 1978; Kansas City, MO, 1979; Minneapolis, MN, 1985.

Federation of American Societies of Experimental Biology - Chicago, IL, 1967; Atlantic City, NH, 1968; Atlantic City, NJ, 1970; Chicago, IL, 1977; Dallas, TX, 1979; Anaheim, CA, 1980; Chicago, IL, 1983; St. Louis, MO, 1984; New Orleans, LA, 1989.

Nebraska Pharmacists Association - Omaha, 1962; Lincoln, 1964; Lincoln, 1973; Omaha, 1985; Kearney, 1989, 1990, 1991, 1992, 1993, 1994; Grand Island, 1995; Lincoln, 1996; Grand Island, 1997, 1998, 1999, 2000, 2002.

International Plant Tissue Culture Conference, State College, PA, 1963.

Sigma Xi Symposium on Mind Altering Drugs, Lincoln, NE 1970.

American Association of Colleges of Pharmacy - Columbus, OH, 1972; Seattle, WA, 1977; Orlando, FL, 1978; Denver, CO, 1979; Boston, MA, 1980; Scottsdale, AR, 1981; Washington, DC, 1983; Portland, OR, 1989; Salt Lake City, UT, 1990; Boston, MA, 1991; Jacksonville, FL, 1992; Washington, DC, 1992; Arlington, VA, 1993; Hilton Head, SC, 1994; Albuquerque, NM, 1994; Washington, DC, 1995; Philadelphia, 1995; Anaheim, CA, 1996; Reno, NV, 1996; Washington, DC, 1997; Indianapolis, IN, 1997; Savannah, GA, 1998; Snowmass, CO, 1998; Washington, DC, 1998; Washington, D.C., 1999; Richmond, VA, 2000; San Diego, CA, 2000; Toronto, Canada, 2001; Toronto, CA, 2001; San Francisco, CA, 2001, Houston, TX, 2002; Kansas City, MO, 2002.

AACP Board of Directors Meeting - Snowmass, CO, 1998; Boston, MA, 1999; Washington, D.C., 1999; Richmond, VA, 2000; San Diego, CA, 2000.

Governor's Workshop on Drug Abuse, Lincoln, NE, 1970.

West-Central States Biochemistry Conference - Manhattan, KS, 1970; Lawrence, KS, 1971; Iowa City, IA 1972.

Drug Abuse Education Workshop for Educators, Lincoln, NE, 1971.

University of Nebraska Management Conference, Lincoln, NE, 1971.

Midwest Regional American Chemical Society Meeting, October, 1973, Lawrence, KS.

Steroid Symposium of the American Oil Chemists Society, September, 1973, Philadelphia, PA.

Nebraska Society of Hospital Pharmacists' Symposium on Clinical Pharmacy, Omaha, NE, 1975.

International Congress of Pharmacology, Helsinki, Finland, 1975; London, England, 1984.

International Conference on Drug Metabolism and Disposition, Turku, Finland, 1975.

International Conference for Research on Medicinal Plants, Munich, West Germany, 1976.

Symposium on "The Pharmacists' Role in the Management of the Hypertensive Patient" sponsored by the Greater Omaha Pharmaceutical Association, Omaha, NE, 1977.

Scientific Sessions of the Annual Nebraska Heart Association Conference, Omaha, NE, 1977.

International Symposium on Microsomes and Drug Oxidations, Ann Arbor, MI, 1978; Brighton, England, 1984.

Symposium on Vitamins: Nutritional Use and Abuse, University of Nebraska Medical Center, Omaha, NE, 1978.

National Sigma Xi Meeting, Toronto, Canada, 1983.

International Symposium on Foreign Compound Metabolism, West Palm Beach, FL, 1983.

National Research Forum on Aging, Lincoln, NE, 1984.

Cold Spring Harbor Laboratory Conference on the Biological Mechanisms of Dioxin Action, Cold Spring Harbor, NY, 1984.

Free Radicals, Pathology and Aging, San Diego, CA, 1985.

Society of Toxicology, San Diego, CA, 1982, 1985; New Orleans, LA, 1986; Washington, D.C., 1987; Dallas, TX, 1988; Atlanta, GA, 1989; Miami, FL, 1990; Dallas, TX, 1991; Seattle, WA, 1992; New Orleans, LA, 1993; Dallas, TX, 1994; Anaheim, CA, 1996; Cincinnati, OH, 1997; Seattle, WA, 1998; New Orleans, LA 1999; Philadelphia, PA, 2000; Salt Lake City, UT, 2003; Baltimore, MD, 2004; New Orleans, LA, 2005; San Diego, CA, 2006; Charlotte, NC, 2007.

International Symposium on Biological Reactive Intermediates, Baltimore, MD, 1985; Tucson, AZ, 1990.

International Congress of Biomedical Gerontology, New York, NY, 1985.

Third Tokyo Symposium on Liver and Aging, Tokyo, Japan, 1986.

Symposium on Frontiers in Aging, Tokyo, Japan, 1986.

Genetic Screening in the Workplace, Omaha, NE, 1986.

International Society for the Study of Xenobiotics, Clearwater, FL, 1987.

19th Annual Magnetic Resonance Conference, NIEHS, Research Triangle Park, NC, 1987.

Tenth International Conference on Organohalogen Compounds, Bayreuth, Federal Republic of Germany, 1990.

Central States Society of Toxicology, Lawrence, KS, 1990; Kansas City, MO, 1992; Omaha, NE, 1993; Kansas City, MO, 1994.

National Association of Retail Druggists, Baltimore, MD, 1991; Seattle, WA, 1992; Boston, MA, 1994.

American Association of Health-System Pharmacists, New Orleans, LA, 1991; Las Vegas, NV, 1995; New Orleans, LA, 1996; Atlanta, GA, 1997; Las Vegas, NV, 1998; Orlando, FL, 1999; Las Vegas, NV, 2000; New Orleans, LA, 2001; Atlanta, GA, 2002.

International Conference on Dioxins, Chaired Session on Role of Hormones, Research Triangle Park, NC, 1991.

Jesuit Conference on Collaboration, Spokane, WA, 1992.

American Pharmaceutical Association, Dallas, TX, 1993; Seattle, WA, 1994; Miami, FL, 1998; San Antonio, TX 1999; Washington, D.C., 2000; San Francisco, CA, 2001; Philadelphia, PA, 2002; Seattle, WA, 2004.

Glaxo/AACP Dean's Leadership Institute, Durham, NC, 1993.

American Physical Therapy Association, Cincinnati, OH, 1993; Seattle, WA, 1999.

International Meeting on Pharmacy and Pharmaceutical Sciences, Istanbul, Turkey, 1994, 1998.

Association of Schools of Allied Health Professions, Galveston, TX, 1993; Richmond, VA, 1994; Milwaukee, WI, 1995; Charleston, SC, 1996; San Diego, CA, 1998; Atlanta, GA, 1999, Norfolk, VA, 2001; San Diego, CA, 2002.

Oxygen Radicals and Antioxidants in Biotechnology and Medicine, Calcutta, India, 1993.

Jesuit Higher Education in the Heartland, Chicago, IL, 1994; St. Louis, MO, 1997; Omaha, NE, 2000.

WorldNutra Conference, Anaheim, CA, 2005; Reno, NV, 2006.

International Society for Nutraceutical and Functional Foods Conference, San Francisco, CA, 2009; Kona, Hawaii, 2012.

Board for the Certification of Nutrition Specialists: Fredericksburg, VA 2010; Chicago, IL 2012, 2013, 2014, 2015.

International Society for Sports Nutrition: Austin, TX 2014.

International Meeting of Pharmacy and Pharmaceutical Sciences, Istanbul, Turkey, 1999, 2002, 2014.

Natural Products Expo, Las Vegas, NV 2013; 2015, 2016

INVITED PAPERS, PRESENTATIONS AND SEMINARS:

1. Over 40 speaking engagements since 1968 to a wide range of civic, social, educational and professional groups on the non-medical use of drugs, and over 100 speaking engagements since 1998 regarding the use of nutraceuticals in health, wellness, weight loss and sports performance.

2. Sigma Xi: Symposium, Center for Continuing Education, University of Nebraska, 1970. "Mind Altering Drugs - Actions and Reactions".

3. Presented a seminar to the College of Pharmacy, University of Pittsburgh on "Steroid Metabolism by Plant Tissue Homogenates", July 1970.

4. Regional Drug Abuse Education Workshop for Educators, Wesleyan University, October 1970. "Commonly Misused Drugs".

5. Hastings College, Interim Course on Drugs, January, 1971. "Pharmacology, Toxicology, Biochemistry, and Chemistry of Hallucinogenic Drugs".

6. Presented a seminar to the School of Pharmacy, University of Washington on "Metabolism of Steroids by Plant Tissue Cultures and Leaf Homogenates", June 1971.

7. Youth Workshop in Drugs, July 1971. Center for Continuing Education, "Pharmacology of Drugs".

8. Presented a seminar to the Department of Biochemistry, UNMC, on "Cardenolide Metabolism", March 1972.

9. Presented a seminar to the Department of Food Science and Technology, UNL, on "Labeling of Vitamin and Mineral Preparations", April 1974.

10. Central States Branch Tissue Culture Association, Inc., Lincoln, Nebraska, April, 1974. "Plant Tissue Culture Methods and Applications".

11. American Oil Chemists Society Steroid Symposium, Philadelphia, Pennsylvania, October 1974. "Plant Tissue Culture Sterols and Sterol Metabolism".

12. Presented a seminar to the Department of Pharmacology, University of Nebraska Medical Center entitled "Cardenolide Metabolism and the Influence of Enzyme Induction", December 1974.

13. Presented a seminar to the College of Pharmacy, University of Minnesota on "In Vitro Cardenolide Metabolism", April 1975.

14. Presented a seminar to Sandoz Toxicology Laboratories, Basle, Switzerland entitled "Stability of Mixed Function Oxygenases", August 1975.

15. Presented a seminar to the Karolinska Institute, Stockholm, Sweden entitled "Some Drug Interactions of Cardiac Glycosides", November 1975.

16. International Congress for Research on Medicinal Plants, Munich, West Germany, September 1976. "Metabolism of Steroids by Plant Tissue Cultures".

17. Presented a seminar to the faculty of UNMC entitled "Isolation of Intestinal Microsomes and Their Metabolism of Xenobiotics", September 1976.

18. Presented a seminar to the faculty of UNMC, November 1976. "Xenobiotic Metabolism by Isolated Intestinal Epithelial Cells."

19. Presented a seminar to the Student American Pharmaceutical Association on "Pharmacy in Sweden", December 1976.

20. Presented a seminar to the Department of Biochemistry, Iowa State University, January 1977. "Metabolism of Xenobiotics by Intestinal Microsomes and Cells".

21. Presented a seminar to the Institute on Aging, University of Nebraska, October 1978. "Tissue Glutathione Levels in Mice as a Function of Age".

22. Participant in Symposium on Vitamins and Nutrition, October 1978. Presentation on "Vitamins: Current Research and Controversy".

23. Presented a seminar to the College of Pharmacy, University of Minnesota on "Xenobiotic Metabolism in Streptozotocin-Diabetic Rats". December 1978.

24. American Association of Colleges of Pharmacy, Denver, Colorado, July, 1979. Symposium presentation entitled "Impact of Clinical Pharmacy on Biological Sciences Instruction: Course Offerings and Student Qualifications."

25. Presented a seminar to the Department of Pharmacology, UNMC, October 1979. "Effects of Various Hormonal Factors on Hepatic and Extrahepatic Mixed Function Monoxygenases."

26. Presented a seminar to the Eppley Institute, UNMC, March 1980. "Studies on Hormonal Factors Influencing the Regulation of Xenobiotic Metabolism".

27. American Association of Colleges of Pharmacy, Boston, Massachusetts, July 1980. Symposium presentation entitled, "Concurrent M.S. - Pharm. D. Program at the University of Nebraska".

28. Presented a seminar to the College of Pharmacy, Yarmouk University, Irbid, Jordan, July 1981 on "Drug and Glutathione Metabolism as a Function of Age".

29. A discussion of "The Effect of Medication on Sexual Functioning" at Immanuel Medical Center symposium on "Sexuality and the Disabled Person", Omaha, Nebraska, September 1981.

30. A lecture to the sophomore medical students, UNMC, in the course on Perspectives on Aging. Lecture entitled "Drugs: metabolism and distribution in the aging person", October, 1981, 1982, 1983, 1984.

31. A seminar presented to the Department of Biochemistry, Creighton University, November, 1981. "Changes in Glutathione and Xenobiotic Metabolism Relative to Age".

32. A symposium lecture entitled "Vitamins, Pseudovitamins, and Non-vitamins" given at the 6th annual Dorsey Symposium, Lincoln, Nebraska, September 1982.

33. Lipid Peroxidation as a Possible Cause of TCDD Toxicity, Eppley Institute, UNMC, April 1983.

34. Role of Glutathione Peroxidase in TCDD Toxicity, Eppley Institute, UNMC, March 1984.

35. Induction of Lipid Peroxidation and Inhibition of Glutathione Peroxidase by TCDD. Banbury Conference on the Biological Mechanisms of Dioxin Action, Cold Spring Harbor, New York, April 1984.

36. A seminar presented to the Chemistry Department, South Dakota State University, October 1984, on "The Human and Animal Toxicity of TCDD".

37. A seminar presented to the Lincoln Branch of the Nebraska Affiliate of the American Heart Association, October 1984, on "The Myocardial Effects of TCDD".

38. A seminar presented to Nebraska Wesleyan University, November 1984, on "Lipid Peroxidation, Glutathione Peroxidase and TCDD Toxicity".

39. Invited speaker at workshop on "Free Radicals, Pathology and Aging", San Diego, California, February 1985. Co-sponsored by the National Institute on Aging and University of California, San Diego. Topic of presentation "Glutathione, DNA Damage and Aging".

40. A seminar presented to the Department of Chemistry, University of Nebraska at Omaha, March 1985, on "TCDD (Agent Orange) Toxicity".

41. Presented a program at UNMC on "Food Facts and Fallacies" as part of the University Lunch and Learn Services, March 1985.

42. A seminar presented at the University of Wyoming on "The Roles of Lipid Peroxidation, Hydrogen Peroxide and Glutathione Peroxidase in Dioxin (TCDD) Toxicity", March 1985.

43. Lecture to the School of Pharmacy, Creighton University on "Graduate Educational Opportunities in the Pharmaceutical Sciences", November 1985, 1986.

44. Invited speaker at the Third Tokyo Symposium on Liver and Aging presentation on "The Role of Glutathione in Aging", August 1986.

45. Presentations to the Nebraska Pharmacists Association State Convention on "The Percutaneous Absorption of Iodochlorhydroxyquin". April 1986.

46. Invited speaker at Conference on Frontiers in Hepatic Aging, in Tokyo, Japan. Presentation on "Glutathione, Free Radicals Antioxidants and Aging", August 1986.

47. A seminar presented at Shionogi Pharmaceuticals Corporation in Osaka, Japan on "The Role of Glutathione Metabolism in Aging", August 1986.

48. A seminar presented to the Departments of Life Sciences and Chemistry at University of Kansas Medical Center on "Glutathione, Free Radicals, Antioxidants and Aging", October 1986.

49. A seminar presented to the South Dakota State University on "Graduate Studies in the Pharmaceutical Sciences", November 1986.

50. A seminar presented to Auburn University College of Pharmacy on "The Role of Iron in TCDD-Induced Toxicity", February 1987.

51. A seminar presented at the National Institute of Environmental Health Sciences on "Factors Involved in TCDD-Induced DNA Damage", November 1987.

52. A seminar presented at Burroughs Wellcome Co., Research Triangle Park, N.C., entitled "The Roles of Iron and Free Radicals in the Hepatotoxicity of TCDD", November 1987.

53. A seminar presented to the Department of Pharmacology, University of North Carolina, entitled "Oxidative Stress and the Toxicity of TCDD", March 1988.

54. A seminar at the University of Montana on "Health Sciences Education: Past, Present and Future", April 1988.

55. A seminar presented at the National Institute of Environmental Health Sciences entitled "AHH Induction and Glucocorticoid Receptor Binding in Skin and Liver of TCDD Treated Mice", June 1988.

56. A seminar presented at Smith Kline & French Laboratories, King of Prussia, PA, entitled "Enzyme Induction and Oxidation Stress by TCDD", July 1988.

57. A seminar presented to the U.S. Army Research Laboratory at Fort Dietrick, Frederick, MD, entitled "The Role of Free Radicals in Hepatotoxicity, and Therapeutic Approaches", July 1988.

58. A presentation of Creighton University entitled "Employment Opportunities in Academia for Pharmacists," 1988, 1989, 1990.

59. A seminar on "The Roles of Free Radicals in Toxicology and Disease" presented at Grinnell College, Iowa, November, 1988.

60. A seminar on "Free Radicals in Toxicology and Disease," Creighton University Health Sciences Center, October, 1989.

61. A seminar on "Production of an Oxidative Stress by TCDD," National Institute of Environmental Health Sciences, June, 1990.

62. A seminar on "Pharmacy Curriculum Development and Curricular Change," Marmara University, Istanbul, Turkey, November, 1991.

63. A seminar on "Pharmaceutical Care and the Clinical Practice of Pharmacy," Marmara University, Istanbul, Turkey, November, 1991.

64. A seminar entitled "The Importance of Bioavailability in Drug Treatment", Hoffmann-LaRoche Pharmaceutical Company, Istanbul, Turkey, November, 1991.

65. A seminar on "Pharmacy Curriculum Development and the Clinical Practice of Pharmacy," Ankara Pharmaceutical Society, Ankara, Turkey, November, 1991.

66. A seminar on "The Role of Free Radicals in Biology and Medicine," Ankara University, Ankara, Turkey, November, 1991.

67. A seminar entitled "Reactive Oxygen Species in Toxicity and Disease," Department of Biochemistry, University of Delhi, Delhi, India, December, 1993.

68. An invited symposium speaker at the International Symposium on Oxygen Radicals and Antioxidants in Biotechnology and Medicine, Calcutta, India, December, 1993. The seminar topic presented was "Oxidative Mechanisms in the Toxicity of Metal Ions."

69. An invited presentation entitled "Hiring for Mission," presented at the Jesuit Higher Education in the Heartland Conference, Chicago, IL, May, 1994.

70. A plenary lecture entitled "The Role of Free Radicals in Toxicity and Disease," presented at the First International Meeting on Pharmacy and Pharmaceutical Sciences, Istanbul, Turkey, September, 1994.

71. The keynote lecture entitled "Curricula for the Present and Future Practice of Pharmacy" at the First International Meeting on Pharmacy and Pharmaceutical Sciences, Istanbul, Turkey, September, 1994.

72. "Mechanisms associated with the toxicity of polyhalogenated cyclic hydrocarbons and heavy metals," presented at the Air Force Office of Scientific Research Predictive Toxicology Program Review, Fairborn, OH, May, 1995.

73. "Considerations involving the establishment of a physician assistant program," presented at the American Association of Colleges of Pharmacy, Philadelphia, PA, July, 1995.

74. "Political, economic, professional and academic realities of our rapidly evolving health care system," presented at the American Occupational Therapy Association, Chicago, IL, April, 1996.

75. "Mechanisms associated with the toxicity of naphthalene, chromium and cadmium," presented at the Air Force Office of Scientific Research Predictive Toxicology Program Review, Fairborn, OH, December, 1996.

76. "Toxicity of metal ions in cigarette smoke," presented at the International Symposium on Damaging Effects of the Oxidants in Cigarette Smoke, Athens, Greece, January, 1997.

77. "The standardization of herbal products," presented at AdvoCare International, Dallas, TX, July, 1998.

78. Invited participant at an American Physical Therapy Association Consensus Conference on Clinical Doctoral Education, Washington, DC, July, 1998.

79. "Toxicity and carcinogenicity of tobacco products: Role of reactive oxygen species and protective effects of antioxidants," presented at the Second International Meeting on Pharmacy and Pharmaceutical Sciences, Istanbul, Turkey, September, 1998.

80. "Successful Transition to the Clinical Doctorate", presented at the American Physical Therapy Association, Seattle, WA, February, 1999.

81. “Free Radical Biology and Chemistry”, presented at the Society of Toxicology, New Orleans, LA, March, 1999.

82. “Educational Requirements and Pharmacy Practice Expectations in the United States”, presented at the Second International Clinical Pharmacy Conference, Amman, Jordan, April, 1999.

83. A Seminar on “Recent Changes in Pharmacy Curricula in the USA” presented at Jordan University for Women, Amman, Jordan, April, 1999.

84. A Seminar on “Role of Free Radicals and Oxidative Stress in Disease and Toxicity” presented at Jordan University, Amman, Jordan, April, 1999.

85. A Seminar on “Toxicity and Carcingenicity of Tobacco Products” presented at Jordan University, Amman, Jordan, April, 1999.

86. “Innovative Collaborative Rural Practice Initiative Among Native Americans in Nebraska presented at NABP-AACP District 5 Meeting, Duluth, MN, August, 1999.

87. Stohs, S.J. and Threlkeld, A. J. The Entry-Level Clinical Doctoral Program in Physical Therapy (DPT). American Physical Therapy Association, 1999. Seattle, WA.

88. Invited speaker and panel member on a program entitled "The Impact of Technology on Creighton University", Omaha, Nebraska, April, 2000.

89. A radio interview on KIOS "Healthwise" concerned with Medical and Medication Errors, April, 2000.

90. Member of Organizing Committee for a Symposium entitled "Academic Organizational Approaches to Transforming Health Science Education". Also chaired session, made a presentation, and served on a panel. Northwestern University, Boston, MA, August, 2000.

91. "An Interdisciplinary Administrative Structure at Creighton University" presented at the Academic Organizational Approaches to Transforming

Health Science Education Conference, Northeastern University, Boston, MA, August, 2000.

92. Oxidative Stress and Toxicity. S. J. Stohs. Central States Society of Toxicology, 2001. Kansas City, Missouri.

93. A radio interview on KFAB "Community Health Watch" on Bioterrorism, Omaha, NE. October, 2001.

94. "Citrus Fruits in Weight Management: Case Studies – Safety and Efficacy of Citrus aurauntium (bitter orange)." S.J. Stohs and H.G. Preuss. WorldNutra 2004 Conference, San Francisco, CA, October, 2004.

95. Invited speaker and panel member for a Symposium entitled, "The Virtual Frontier: Developing and Delivering Health science Education from a Distance." Creighton University, Omaha, NE, June, 2005.

96. "Selected Nutrients In Muscle Atrophy And Advancing Age-Related Disorders" presented at the WorldNutra 2005 Conference. Anaheim, CA. October, 2005.

97. "Dietary Supplements: Safety and Efficacy" presented to the Long Island University College of Pharmacy, Long Island, NY, November, 2007.

98. "Are Non-nutritive Sweeteners as Safe as Sugars?" presented at the American College of Nutrition, Orlando, FL, October, 2009.

99. "Safety and Efficacy of Super CitriMax(hydroxycitric acid-SX), a Novel Weight Loss Supplement Derived from *Garcinia cambogia*," presented at the International Society for Nutraceutical and Functional Foods, San Francisco, CA, Novemberr, 2009.

100. "Weight Loss/Weight Management, Increased Vitamin D and Decreased Salt: Solutions to Rising healthcare Costs" presented at Long Island University School of Pharmacy, Brooklyn, NY, April, 2010.

101. "Are Non-Nutritive Sweeteners as Safe as Sugars or are Sugars as Safe as Non-Nutritive Sweeteners?" presented at Long Island University, Brooklyn, NY, April 2010.

102. "Perspectives on Non-Sugar Sweetreners" presented at Georgetown University, Washington, DC, April 2010.

103. "The Safety and Efficacy of Bitter Ornage Extract and its Primary Protoalkaloid p-Synephrine". Iovate Nutraceuticals, Toronto Canada, August 2011.

OTHER ACTIVITIES:

1. Co-author of an article in the Supplement of the October 4, 1970 Lincoln Sunday Journal and Star on drug abuse entitled "Another View". Also in this supplement an outline of the commonly abused drugs, their effects and dangers.

2. Governor's Commission on Drug Abuse for the State of Nebraska, and co-chairman of the Education Subcommittee thereof, 1970-71. Nebraska State Commission on Drugs and member of the Grant Reviews and Evaluations Subcommittees, 1971-72. As a member of the Commission on Drugs:

   A. Established recommended films on drugs for primary and intermediate grades, junior high, high school, college, and adult and professional levels - for general distribution throughout the State, 1970. Revised 1971.

   B. Evaluated existing drug information materials and established a list of recommended reference materials, 1970. Revised 1971.

   C. Made available to the physicians, hospitals, and clinics of the State a manual entitled "Drug Abuse Acute Treatment Manual." 1971.

   D. Coordinated and compiled drug education materials for "DRUG ABUSE, An Authoritative Selected List of Materials," published by the Nebraska Public Library Commission and the Nebraska State Commission on Drugs, 1971. Revised in 1972.

3. Developed an outline on "Mind Altering Drugs - Actions and Reactions" which covers the chemistry, sources, pharmacology, psychopharmacology, toxicology, doses, dosage forms, and therapeutic applications of the commonly used and misused mind-altering drugs for continuing education.

4. Developed an outline of the potential symptoms of the use of heroin, barbiturates, glues, and solvents, marijuana, hallucinogens (LSD), and amphetamines for continuing education.

5. The establishment of a drug education committee, the teaching and training of interested pharmacy students to go out and speak on drugs, and a drug information service with Drs. E.B. Roche and R.W. Piepho, 1969-74.

6. Member of the University Lutheran Chapel Planning and Building Committee, University of Nebraska, Lincoln, Nebraska, 1968-71, which resulted in the building of a new facility on the UNL campus.

7. Development of an integrated three-semester course sequence in biochemistry and natural products for pharmacy students. Complete revision and updating of the laboratory equipment and facilities, 1968-71.

8. Drafted the By-Laws for the College of Pharmacy, 1973.

9. Coordinator of the Graduate Programs of the College of Pharmacy, 1972-75.

10. Coordinator of the Visiting Scientists Programs of the College of Pharmacy, 1972-75.

11. Developed a required three-credit course in Clinical Chemistry and Biochemistry, 1973, with Dr. H. Rosenberg.

12. Drafted the procedure whereby the three graduate degree granting departments from within the College of Pharmacy could be incorporated into the Interdepartmental Area of Medical Sciences, and successfully negotiated this incorporation, 1972-73.

13. Provided and supervised a tape-recorded, 2 credit, self-paced, elective course entitled "Systems of Defense," 1974-1985.

14. Developed and reorganized a required two quarter, 8 credit course in Pharmaceutical Biochemistry, 1976, with Dr. H. Rosenberg and Dr. W. Murray.

15. Reorganized the graduate level courses in the Department, 1976.

16. Final Judge of Student Presentations at UNMC Student Research Forum, September 1976.

17. Developed a 1 credit elective course "Modified Basic and Advanced Life Support for Pharmacists," 1977.

18. Final Judge of Student Presentations at UNMC Student Research Forum, 1977.

19. Discussion Leader on Drug Metabolism at Annual Midwest Student Medical Research Forum, Omaha, Nebraska, 1978.

20. Developed and coordinated a required 6 quarter credit hour course in Chemotherapy, 1978. Revised to 4 sem. credit hours in 1982.

21. Presented a continuing education course on New Drugs to Pharmacists at Scottsbluff, Nebraska and Lincoln, Nebraska, April 1978.

22. Member of Advisory Committee for Health Resources Administration Contract 232-7E 0908 entitled "Alternative Methods by Which Basic Sciences Pharmacy Faculty can Relate to Clinical Practice," College of Pharmacy, University of Minnesota, 1978-79.

23. Presented lectures on Cancer Chemotherapy for Lincoln Medical Education Foundation program for School Nurses Update. Lincoln, Nebraska, June 1979.

24. Abstract and Manuscript Judge for UNMC Student Research Forum, 1979.

25. Presented three lectures on drug metabolism to graduate students in Enzymes Course, Department of Biochemistry, Creighton University, 1979.

26. Vice President, First Lutheran Church, Omaha, NE 1978-79. President First Lutheran Church, Omaha, NE 1979-81 and 1985-87.

27. Member of Site Visit Team, NIH Minority Biomedical Support (MBS) Grant Application, School of Pharmacy, Florida A&M University, Sept 21-23, 1980.

28. Invited to Jordan to negotiate an exchange agreement between the College of Pharmacy, Yarmouk University and the University of Nebraska Medical Center College of Pharmacy.

29. Grant Reviewer for NCI National Large Bowel Cancer Project, January, 1982.

30. Developed a graduate level course in Drug Metabolism and Disposition, UNMC, 1982.

31. Developed a course in nutrition and diet therapy, UNMC, 1983.

32. Member of Review Panel, NIH Minority Biomedical Research Support (MBRS) Program, Washington, D.C. Sept. 28-30, 1983.

33. Session Moderator at the National Research Forum on Aging, Feb. 22-24, 1984, Lincoln, NE.

34. Invited Participant at the Banbury Center of Cold Spring Harbor Laboratory Conference on the Biological Mechanisms of Dioxin Action, April 1-4, 1984.

35. Final Judge of Student Presentations at Student Research Forum, UNMC, 1984.

36. Invited participant at a workshop on Free Radicals, Pathology and Aging, sponsored by the National Institute on Aging, February 16, 1985, San Diego, CA.

37. Special Grant Reviewer for National Institute on Aging, March, 1985.

38. Visiting Professor, Faculty of Pharmacy, Tanta University, Tanta Egypt, April 1985. Presented a series of research related seminars, assisted with cirriculum development, and worked with graduate students in the development of research projects. In Egypt, lectures were also presented at Cario University, Assiut University, Alexandria University and Zagazig University.

39. Invited to Jordan's Yarmouk University and Jordan University Faculties of Pharmacy, May 1985. Worked with faculty on curriculum development and research projects of mutual interest.

40. Member of Review Panel, NIH Minority Biomedical Research Support (MBRS) Program, Washington, D.C., July, 1985.

41. Radio interviews concerning proposed closing of College of Pharmacy, July, 1985; KFAB, KGRI, KNEB, KLIN, KRNY, and Light 96.

42. Interviews concerning vioform research, July, 1985. National Public Radio, KFAB, KFOR, Z92, KGRI, NBC-Chicago, UPI-Lincoln, Washington Post, Medical Letter, Omaha World Herald, Lincoln Star, Bruce Prentosil Channel 6, WOWT (Channel 6) Morning Show.

43. Radio Interview on Research in the College of Pharmacy, UNMC, July, 1985, Z92/KEDS.

44. Presentation to the Goodfellowship Club, Omaha, NE, August, 1985, on "The College of Pharmacy as an Integral Component of a Medical Center."

45. NIH Site Visit Team for Minority Biomedical Research Support Program at California State University, Long Beach, CA. Oct. 1985.

46. Expert witness before FDA Dermatology Panel, Washington, D.C. Nov. 1985. Testified concerning a petition on the removal of iodochlorhydroxyquin from the market. The petition submitted by the Health Research Group was based primarily on studies reported in Publications #100 and 102 by Stohs et al. The Panel voted unanimously to recommend removing the drug as an over-the-counter product and restrict its use to prescription only.

47. Member of Review Panel, NIH Minority Biomedical Research Support Program, Washington, D.C. January 1986.

48. NIH Site Visit Team and Review Panel for Research Centers in Minority Institutions (RCMI) Program at Xavier University, New Orleans, LA, April 1988.

49. Interview on Channel 6 TV "Alive at Five" Program with Gary Kerr and Dave Webber on "Steroid Use by Athletes," Sept., 1988.

50. NIH Site Visit Team and Chairman of Review Panel for Research Centers in Minority Institutions (RCMI) Program at Florida A&M University, Miami and Tallahassee, FL, Feb., 1990.

51. NIH Study Section for Research Centers in Minority Institutions (RCMI) Grant Program, Washington, DC, March, 1990.

52. Reviewed graduate program at Mercer University, Atlanta, GA, April, 1991.

53. N.I.H. Study Section for Research Centers in Minority Institutions (RCMI) grant program, Washington, D.C., March, 1992.

54. Initiated revision of the School Grade Appeals Policy, By-Laws, Scholastic Standing Policy, and Misconduct Policy, Creighton University (1991-92).

55. Established Industrial Advisory Committee, and re-established Alumni Advisory Board, Creighton University, 1991.

56. Established Post-B.S. Pharm.D. recruitment program, hired additional student recruiter and expanded student recruitment efforts, 1991.

57. Established grant review procedure and Grant Review Committee, and established a Faculty and Staff Development Committee, Creighton University, 1991.

58. Remodeled faculty offices, computer laboratory, and Admissions Department offices, Creighton University, 1991.

59. Developed rural health student recruiting agreements with Chadron State College and Wayne State College, 1991.

60. Established faculty, student and research exchange agreement with Marmara University, Istanbul, Turkey, and Creighton University, 1992.

61. Chaired the School Strategic Planning and Implementation Committee, Creighton University, for the Year 2000, being directly responsible for the implementation of the strategic goals which were set forth, 1990-91.

62. Initiated and promoted curriculum revision in pharmacy based on outcome objectives which were established by the faculty at a series of all-faculty retreats. Faculty approved new Pharm.D. curriculum for Creighton University, 1992.

63. Initiated the establishment of Phi Lambda Sigma, National Pharmacy Leadership Honor Society chapter, at Creighton University, 1992.

64. Initiated the development of an advanced degree program in occupational therapy, and hired new faculty in occupational therapy at Creighton University, 1992.

65. Worked with alumni to solicit funds for the Sebastian Pirruccello Scholarship (raised over $50,000), and organized the Sebastian Pirruccello Recognition Dinner at Creighton University, 1992.

66. Organized the establishment of a Department of Physical Therapy, and hired a Director in 1992. Secured approval to offer the first entry-level clinical doctorate (Doctor of Physical Therapy) in 1992, with the first class entering in the fall of 1993. First class of 48 students entered in the fall of 1993. Established the first entry-level Doctor of Physical Therapy program in the country at Creighton University.

67. Initiated the inclusion of Occupational Therapy students in the Creighton University Summer program in the Dominican Republic to provide service, cultural immersion and reflection beginning in 1993.

68. Secured approval to adopt the Doctor of Pharmacy degree as the sole professional degree with the entering class in 1994 at Creighton University.

69. Secured Creighton University approval to establish a Non-traditional Doctor of Pharmacy program, 1993. First students enrolled in May, 1994.

70. Member of Organizing Committee for International Symposium on Oxygen Radicals in Biotechnology and Medicine, Calcutta, India, 1993.

71. Member of Organizing Committee for International Symposium on Pharmacy and Pharmaceutical Sciences, Istanbul, Turkey, 1994. Gave keynote lecture.

72. Secured Creighton University approval to establish a post professional (baccalaureeate or masters degree) Doctor of Occupational Therapy (OTD) program with the first students being admitted in the fall of 1995. The program is one of the first clinical doctoral programs in occupational therapy in the country.

73. Guest editor of a special issue of the Journal of Basic and Clinical Physiology and Pharmacology 6, 1995.

74. Served as a consultant to the Assistant Secretary of Health, U.S. Department of Health and Human Services, regarding the future of academic health centers and the role of pharmacy and allied health professions in academic health centers, October, 1996.

75. Secured Creighton University approval to establish a M.S. degree in pharmaceutical sciences, December, 1996.

76. Initiated the inclusion of Physical Therapy students in the Creighton University Summer program in the Dominican Republic to provide service, cultural emersion and reflection beginning in 1996.

77. Appointed to the International Advisory Board, Research Institute of Preventive and Environmental Medicine and Biotechnology, Athens, Greece, 1997.

78. Raised approximately $165,000 toward the renovation of a clinical education center at Creighton University. Funds were raised through solicitations of alumni, pharmaceutical corporations and friends of the School. 1995-1998.

79. Solicited funds for the establishment of fourteen endowed scholarships (minimum of $25,000 each) for students in the School of Pharmacy and Health Professions, Creighton University. Funds solicited from corporations, alumni and friends of the University. 1993-2003.

80. Procured the establishment of an endowed scholarship from Hoffmann-La Roche Corporation in the amount of $250,000 for minority students, Creighton University. 1994-1998.

81. Member of Organizing Committee for International Symposium on Pharmacy and Pharmaceutical Sciences, Istanbul, Turkey, 1998. Gave initial lecture to start the conference.

82. Member of an organizing committee for an International Symposium on Clinical Pharmacy, Amman, Jordan, 1999.

83. Initiated the first entry-level Clinical Doctoral program in Occupational Therapy in the country with the class of students entering in the fall of 1999 at Creighton University.

84. Established an agreement with the College of Business Administration to offer a combined Doctor of Pharmacy/MBA program in 1999 at Creighton University. This program replaced a previously negotiated program which had attracted very few students because it was participant unfriendly.

85. Initiated the first Non-Traditional, Transitional Doctor of Physical Therapy program in the country in the fall of 1999 at Creighton University.

86. An editorial in the Omaha World Hearld concerning the role of Pharmacists in the prevention of medication errors, February 10, 2000.

87. An editorial in the Omaha World Hearld concerning the national shortage of Pharmacists, December 29, 2000.

88. Initiated the first non-traditional Doctor of Occupational Therapy pathway in the country in the fall of 2001 at Creighton University.

89. Initiated the nation's first entry-level web-assisted Doctor of Pharmacy pathway in the fall of 2001 at Creighton University. All didactic courses in the pathway are available via Internet and CD Rom technology.

90. An editorial in the Omaha World Herald concerning the failures of Medicare prescription discount card programs. Worked with U.S. Senator Chuck Hagels' office to develop legislation for a prescription drug benefit. August 10, 2001.

91. Consultant to the Scientific Advisory Board of the United States Environmental Protection Agency, 1996-2001.

92. Consultant to the National Institute of Environmental Health Sciences for the preparation of a background document on the carcinogenicity of naphthalene, 2001.

93. Member of the Creighton University Steering Committee for the design and building of the new integrated science building which included a new administrative suite for the School and approximately 60 offices for pharmacy faculty as well as two departmental administrative suites. Moved into new facilties in December 2002.

94. Established one of the first residency programs for physical therapy in the nation at Creighton University Medical Center, July, 2003.

95. Initiated the development of a B.S. in Phamacy, Physical Therapy and Occupational Therapy students enrolled in Doctoral programs at Creighton University Medical Center, beginning in the Fall of 2003.

96. Responsible for the development of a Research & Development program at AdvoCare International L.P., hiring individuals in product development, formulation, regulatory affairs and package engineering, 2003 – 2004.

97. Responsible for establishing and developing back-up manufacturers for over 50 AdvoCare products while developing new products for market, 2003 – 2005.

98. Site visits to the following manufacturing facilities during 2004 – 2007: Vitarich, Interactive Nutrition, Arizona Nutritional Supplements (ANS), American Nutritional Corporation (ANC), National Vitamin Company (NVC), Nellson Nutraceuticals, Natural Alternatives International (NAI), Custom Nutrition Laboratories (CNL), Biozone Laboratories, Protec Laboratories, Progressive Laboratories, Cornerstone Research & Development, ELAN Nutrition, and We-Pack-It-All.

99. From 1998-2014 participated in over 40 AdvoCare Success Schools, providing product training and interfacing with Distributors, speaking to as many as 25,000.

100. From 1998-2014, gave numerous AdvoCare product training programs around the country including in Texas, Colorado, Florida, Washington, California, Michigan, Nebraska, Iowa, Illinois, Tennessee, Georgia, South Carolina, South Dakota, Missouri, Mississippi, Alabama, Oklahoma, Kentucky, Virginia, Washington, Oregon, and Hawaii.

101. Established and coordinated a symposium on "dietary supplement safety" at the annual meeting of the American College of Nutrition, Orlando, FL, 2007.

102. Applied for patents on behalf of AdvoCare for 3 products between 2005 – 2006.

103. Between 2004–2008, was responsible for developing over 25 new AdvoCare products and making improvements to over 40 products based on the latest science.

104. Participated in a series of radio talk shows on KCFO (AM970) regarding nutrition, particularly for senior citizens, 2007.

105. Responsible for coordinating research on a series of AdvoCare products including MNS Orange, MNS Platinum, A-Supreme, ThermoPlus, Carb-Ease, SPARK Energy Drink, Rehydrate Electrolyte Replacement Drink, Muscle Fuel, and the glycemic indices of all AdvoCare drinks, shakes and bars, 2003-2008.

106. Responsible for ultimate development of quality assurance/quality control procedures, adverse events management and procedures, clinical assessment of products, product launch and elimination procedures and other general operating procedures within AdvoCare's R&D department, 2003-2005.

107. Appointed to the Certification Board for Nutrition Specialists, 2004 – 2007, a national nutrition certification program. Reappointed in 2008. Vice – Chair for Administration 2009-2010. Served as President from 2011-2014.

108. Participated in various AdvoCare distributor incentive trips: Australia and New Zealand, 2002; Maui, Hawaii, 2004; Lake Louise, Canada, 2004; Little Palm Island, FL, 2005; San Francisco, CA, 2006; New York City, NY, 2006; Alaska Cruise, 2007; Peter Island, 2009; Paris, 2013; Mediterranean, 2014.

109. For the American College of Nutrition (2008-2009), served as the chief scribe for revision of By-Laws and the Standing Committee Procedures document. Drafted a Strategic Planning document. Chaired the Publications Committee, resulting in a change in publishers for the Journal of the American College of

Nutrition with significant savings. Revised and updated the Editorial Board of the Journal, and instituted co-editors.

110. Consultant for Nutratech/Novel ingredients 2009-present. Traveled and gave presentations in California, New Jersey, New York, Utah, Colorado, Texas, Illinois.

COMMITTEES:

University of Nebraska-Lincoln:

Faculty Health Council, 1967 - 71
Marshalling Corps, 1968 - 70
Nebraska College Opportunity Ad Hoc Committee, 1970 - 71
Ad Hoc Committee to Recommend Changes in the Structure and Operation of the Senate, 1969
Liaison Committee, 1970-73, Secretary, 1971 - 72
Search Committee for Vice-Chancellor of Academic Affairs, 1972

University of Nebraska System:

Executive Graduate Council, 1973 - 75
Executive Graduate Council, 1985 - 87
Executive Committee of the Executive Graduate Council, 1986 - 87

College of Pharmacy - University of Nebraska:

Admission and Scholarship Review, 1968 - 71
Course of Study, 1967 - 72
Grade Appeals, 1968 - 72
Curriculum Committee, 1968 - 74
Departmental Graduate Committee, 1968 - 84
Pharmaceutical Sciences Area Graduate Committee, 1969 - 74
Search Committee for a Dean of the College, 1971
Ad Hoc Committee on Promotion and Tenure, 1971
Space Utilization Committee, 1972 - 76
Executive Committee, 1972 - 1987
Ad Hoc Faculty Policies and Procedures Committee, Chairman, 1973
Teaching Improvement Committee, 1974 - 75
Ad Hoc Committee on NCACS Accreditation, 1976
Search Committee for Chairman, Dept. of Pharmacodynamics and Toxicology, 1979
ACPE Accreditation Self-Study Review Committee, 1979
Continuing Education Committee, 1978 - 85, 1986 - 87
Self-Study Role and Mission Subcommittee, Chairman, 1985
Self-Study Budget and Finance Subcommittee, 1985
Safety Committee, 1984 - 87
GAPS Grant Review Committee, 1985 - 86
Strategic Planning Committee, 1986 - 87
Long-Range Planning Committee, 1983 - 85

Pharmaceutical Sciences Graduate Program Committee, 1983 - 87
Ad Hoc By-Laws Committee 1983 - 84

University of Nebraska Medical Center:

Pre-Clinical Seed Grant Review Committee, 1972
Ad Hoc Committee on the Academic Organization of the Medical Center, 1973 - 74
Medical Sciences Area Graduate Committee, 1973 - 1984
University Graduate Council, Medical Center Representative, 1973 - 74
Ad Hoc Committee for Organization of Medical Center Senate, 1974
Seed Grant Review Committee, 1974 - 76
Liaison Committee, 1975 - 76
Systems Office Task Force on Travel, Moving, and Recruitment Expenses, Medical Center Representative, 1975 - 76
Ad Hoc Committee on Graduate Fellowships, 1975 - 76
Graduate Council, 1977 - 79
Ad Hoc Committee on Selecting a Grants Manager, 1977
Chancellor's Ad Hoc Task Force on Research, 1977 - 79
Chancellor's Ad Hoc Oncology Program Committee, 1977 - 1979
Search Committee for a Dean of College of Medicine, 1978
Search Committee for a Dean of Graduate Studies and Research, 1978 - 79
Ad Hoc Continuing Education Committee on Gerontology, 1979
Faculty Senate Grievance Committee, 1979-82; Chairman 1981 - 82
Clinical Cancer Education Committee, 1980 - 1984
Cell Sorter Facility Policy Committee, 1980 - 1984
Search Committee for Director of Eppley Institute, 1981 - 82
UNMC Special Functions Committee 1981-1982, 1984 - 85
LB 506 Grant Reviews Committee, 1982, 1983, 1984, 1986
Chancellor's Task Force on Nutrition, 1984 - 85
Executive Graduate Council, 1985 - 87
Bulk Purchasing Committee, 1985 - 86
First Professional Degree Committee, 1985 - 86
Marshalling Corps, 1982 - 86
Tenure Review Committee, 1985 - 86
Board of Directors, Toxicology Program, 1985 - 1989
Faculty Senate Academic Freedom and Tenure Committee, 1986 - 87
Chancellor's Planning Committee, 1986 - 1987
Search Committee for Dean of College of Pharmacy, 1986

School of Pharmacy and Allied Health - Creighton University:

Administrative Committee, 1989 - 2003
Executive Committee, 1989 - 2003
Pharmacy Curriculum Committee, 1989 - 1992
Grade Appeals Committee, 1989 - 1990
Scholastic Standing Committee, Chairman, 1989 - 1990
Pharmacy Accreditation Self-Study Steering Committee, 1989 - 1991
Finance Subcommittee, Chairman

Faculty and Staff Subcommittee, Chairman
Creighton in the Year 2000 Planning Committee, Chairman, 1990
Occupational Therapy Admissions Committee, 1990 - 2003
Pharmacy Admissions Committee, 1990 - 2003
Alumni Advisory Board, Chair, 1990 - 2003
Strategic Planning and Implementation Committee, 1991 - 2003
Physical Therapy Admissions Committee, 1992 - 2003
Industrial Advisory Board, Chair, 1992 - 2003

Creighton University:

Health Sciences Center Safety Committee, 1989 - 1992
International Students Committee, 1989 - 1991
Planning Steering Committee, Creighton in the Year 2000, 1990 - 1992; 1994 - 1996
Academic Council, 1990 - 2003
Academic Leadership Committee, 1990 - 2003
Council of Deans, 1990-present; Chair – 1996 - 97
Grant Review Committee, 1990 - 1992
Search Committee for Academic Vice President, 1993
Search Committee for Assistant Grants Administrator, 1993
Search Committee for the Dean, School of Dentistry, Chairman, 1993 - 94

Process Redesign Advisory Committee, 1996 - 97
Steering Committee for the Center for Practice Improvement and Outcomes Research, 1996 - 2003
Budget Redesign Advisory Committee, 1997 - 98
Cancer Center Advisory Board, 1995 - 98
Budget Design Planning Advisory Committee, 1997
Academic Process Redesign Committee, 1997 - 98
Center for Health Policy and Ethics Deans Advisory Council, 1996 - 2003
Search Committee for the Dean, Chairman, School of Law, 1998 - 99
Cancer and Smoking Disease Research Program Advisory Committee, 1998 - 2003
Strategic Planning - Beyond Creighton 2000 Committee #1, Chair, 1998 - 99
Student Information Systems Coordinating Committee, 1999 - 2001.
Creighton University Strategic Planning Committee, 1999 - 2000.
Creighton University Strategic Planning Academic Excellence Subcommittee, 2001
Biomedical Research Advisory Council, 2002 - 2003
Science Complex Steering Committee, 2000 - 2003
HIPAA Steering Committee, 2002 - 2003
Search Committee for Vice President University Relations, 2002 - 2003

State:

Governor's Commission on Drug Abuse, 1970 - 71
State Commission on Drugs, 1971 - 72
Research Committee of the Nebraska Heart Association, 1973 - 76
Sigma Xi Faculty & Graduate Student Outstanding Scientist Awards Committee, 1979
Nebraska Chapter of Sigma Xi President-Elect, 1983-84; President, 1984 - 85
State Board of Pharmacy's Review Committee for Continuing Pharmacy Education 1984 - 87
Nebraska Pharmacy Strategic Planning Committee, 1994 - 96
Nebraska Pharmacy Coordinating Council, 1996 - 2003
Creighton Federal Credit Union, 1997 - 2001
Nebraska Pharmacists Association Legislative Committee, 1997 - 2002

National:

Scientific Program Committee of the Pharmacognosy and National Products, Section of the Academy of Pharmaceutical Sciences, 1970 - 71
Chairman of the Scientific Program Committee of the American Society of Pharmacognosy, 1972 - 73
Chairman of the Kilmer Prize Committee of the Pharmacognosy and Natural Products Section of the Academy of Pharmaceutical Sciences, 1973 - 74
Chairman, Special Projects Grant Committee, American Association of Colleges of Pharmacy, 1983 - 85
Resolution Committee, American Society of Pharmacognosy, 1973 - 74
American Association of Colleges of Pharmacy, Section of Teachers of Biological Sciences Nominating Committee Chairman, 1974 - 75
Committee on Long-Range Goals, Pharmacognosy and Natural Products Section of the Academy of Pharmaceutical Sciences, 1977 - 78
Chairman, Resolutions Committee, Biological Sciences Section, American Association of Colleges of Pharmacy, 1978 - 79
Chairperson-Elect, 1979 - 80, Biological Sciences Section of The American Association of Colleges of Pharmacy
Kilmer Prize Committee, Academy of Pharmaceutical Sciences, 1979
Advisory Committee for HRA Contract 232-7E 0908, University of Minnesota, 1978 - 79
Kilmer Prize Committee, Academy of Pharmaceutical Sciences, 1980 - 82
Chairman, Kilmer Prize Committee, Academy of Pharmaceutical Sciences, 1980 - 81
Chairman, Biological Sciences Section, American Association of Colleges of Pharmacy, 1980 - 81
Site Visit Team, NIH Minority Biomedical Research Support (MBRS) Grant Application for School of Pharmacy, Florida A & M Univ., Sept 21 - 23, 1980
Distinguished Pharmacy Education Award Committee, American Association of Colleges of Pharmacy, 1982 - 83
Chairman, Nominating Committee, Biological Sciences Section of the American Association of Colleges of Pharmacy 1982 - 83, 1983 - 84, 1984 - 85

Secretary, Council of Sections of the American Association of Colleges of Pharmacy, 1982 - 83
American Association of Colleges of Pharmacy Council of Faculties, Faculty Development Committee, 1984 - 85
Site Visit Team, NIH Minority Biomedical Research Support (MBRS) Grant Application for program at California State University, Long Beach, CA, 1985
Review Panel, NIA Minority Biomedical Research Support Program, Washington, DC, 1985, 1986
Review Panel, NIH Research Centers in Minority Institutions (RCMI), 1988
APhA Academy of Pharmaceutical Sciences Selection Committee for the Research Achievement Award in Pharmacodynamics, 1988 - 89
Society of Toxicology Central States Chapter Program Committee, 1990
Review Panel, Chairman, NIH Research Centers in Minority Institutions (RCMI), 1990
Nominating Committee, Biological Sciences Section of the American Association of Colleges of Pharmacy, 1990 - 91
Central States Chapter of the Society of Toxicology
Vice President, 1991 - 92
President-Elect, 1992 - 93
President, 1993 - 94
Technical Committee, Society of Toxicology, 1990 - 92
Environmental Protection Agency Dioxin Science Advisory Board, 1995 - 96
Ethics Committee, Association of Schools of Allied Health Professions, 1994 - 96
USP Division of Standards Development Advisory Panel on Identification and Standardization of Natural Products, 1995 - 2000.
American Association of Colleges of Pharmacy Special Committee to Study Structure and Process, 1995 - 98
American Association of Colleges of Pharmacy Institutional Research Advisory Committee, 1996 - 97
NIEHS Special Emphasis Panel, 1997, Chair
Board of Directors, American Association of Colleges of Pharmacy, 1998 - 2001
American Association of Colleges of Pharmacy Private Schools and Colleges Forum, Secretary – 1994 - 96; Chair, 1996 - 98
Site Visit Team for Accreditation in Physical Therapy, University of Washington, Seattle, WA, 2002.
Site Visit Team for Accreditation in Physical Therapy, Bellarmine University, Louisville, KY, 2004.
Elected member of the Certification Board for Nutrition Specialists, 2004, re-elected 2007.
American College of Nutrition 21st Century Steering Committee,subcommittees on By-Laws, Structure, and Development, 2008-2009.
Chairman, American College of Nutrition Publications Committee, 2008-2009

RESEARCH SUPPORT, GRANTS AND CONTRACTS RECEIVED:

1. Smith, Kline and French Foundation Award of $6750 for the purchase of a liquid scintillation counter, 1968.

2. University of Nebraska Research Council Award of $3190 for the purchase of a high speed refrigerated centrifuge, 1968.

3. Nebraska Heart Association Grant of $2070 for a study on "The Metabolism of 14C-Cholesterol in Dioscorea Tissue Suspension Cultures". July 1, 1968 - June 30, 1969.

4. Nebraska Heart Association Grant of $1665 for an investigation of the "Metabolism of Heart Glycosides by Cardiac and Hepatic Microsomes". September 1, 1968 - August 31, 1969.

5. National Science Foundation Grant of $11,200 for an investigation entitled, "Studies on Cholesterol Side Chain Cleavage Enzymes in Cardenolide Biosynthesis." September 1, 1969 - August 31, 1971.

6. Public Health Service Grant of $24,406 for an investigation on the "Production and Biosynthesis of Medicinals by Plants." November 1, 1969 - October 31, 1972.

7. Nebraska Heart Association Grant of $4300 for an investigation entitled "In Vitro Studies on Cardiac Glycoside Metabolism". July 1, 1971 - June 30, 1972.

8. National Science Foundation Grant of $12,000 for "Sterol Side Chain Cleavage and Cardenolide Biosynthesis in Cardenolide Producing Plants". January 1, 1971 - December 30, 1973.

9. Nebraska Heart Association Grant of $6600 for an investigation entitled, "In Vitro Studies on Cardenolide Metabolism". July 1, 1972 - June 30, 1973.

10. University of Nebraska Medical Center Seed Grant of $3820 for "Preliminary Studies on the Mechanism of Action of PCN." November 1, 1972 - June 30, 1973.

11. Nebraska Heart Association Grant of $5090 for an investigation entitled "PCN Mechanism of Protection from Digitalis Toxicity." July 1, 1973 - June 30, 1974.

12. Lincoln-Lancaster Drug Projects Contract for approximately $2500 to "Conduct Routine Urinalysis for Drugs for 'Full Circle' Staff and Residents." Co-sponsored with Dr. E.B. Roche, December 1, 1973 - June 30, 1974. Renewed for July 1, 1974 - December 31, 1974.

13. Nebraska Heart Association Grant of $4695 for an investigation entitled "Blood Level Determinations of Thiazide Diuretics." July 1, 1974 - June 30, 1975.

14. ConAgra Corporation contract of $9490 for a study on "The Growth of Selected Microorganisms on Oat Hulls as a Potential Source of Protein." September 1, 1974 - August 31, 1975. Co-principal investigator with Dr. H. Rosenberg.

15. University of Nebraska Medical Center Seed Grant of $4675 for an investigation on "The Growth of Microorganisms on Agricultural Wastes as a Source of Utilizable Protein." July 1, 1974 - June 30, 1975. Co-principal investigator with Dr. D. H. Rosenberg.

16. University of Nebraska Medical Center Seed Grant of $2100 to conduct "An Evaluation of the Physiological and Metabolic Changes Associated with

Chronic Methaqualone Abuse." July 1, 1974 - June 30, 1975. Co-principal investigator with Dr. R.W. Piepho.

17. Nebraska Heart Association Grant of $4852 for the study on "Blood Level Determinations of Thiazide Diuretics." July 1, 1975 - June 30, 1976.

18. ConAgra Corporation contract of $3090 for a study on "The Growth of Selected Microorganisms as a Potential Source of Protein on Carbohydrate Extracts Obtained from Oat Hulls." September 1, 1975 - March 1, 1976. Co-principal investigator with Dr. H. Rosenberg.

19. Nebraska Heart Association Grant of $5310 for an investigation on the "Metabolism of Quinidine-Like Antiarrhythmic Agents". July 1, 1977 - June 30, 1978.

20. University of Nebraska Medical Center Seed Grant of $4949 for an investigation entitled "The Mechanism and Significance of Intestinal Drug Metabolism". July 1, 1977 - June 30, 1978.

21. Center on Aging Grant of $1980 to initiate a project entitled "Glutathione Levels in Rat Hepatic and Extrahepatic Tissues as a Function of Age." March 1, 1978 - September 30, 1978.

22. Nebraska Heart Association Grant of $5840 to continue our investigation on the "Metabolism of Quinidine-Like Antiarrhythmic Drugs." July 1, 1978 to June 30, 1979.

23. University of Nebraska Medical Center Seed Grant of $7442 for a project entitled "Glutathione Levels and Xenobiotic Metabolism in Hepatic and Extrahepatic Tissues as a Function of Age." July 1, 1978 - June 30, 1979.

24. Center on Aging Grant of $1900 to initiate a project entitled "Xenobiotic Metabolism in Hepatic and Extrahepatic Tissues as a Function of Age." November 15, 1978 - September 30, 1979.

25. Public Health Service Grant for $68,238 entitled "Childhood Lead, Pyrimidines and Metabolic Debris." April 1, 1978 - March 31, 1980. Associate Investigator. Dr. Carol Angle - Principal Investigator.

26. Nebraska Heart Association Grant of $5965 for a study entitled "Lithium and Cardiac Rhythm, Electrolytes and ATPase." July 1, 1979 - June 30, 1980.

27. National Institute on Aging (PHS) Grant for $75,859 entitled "Glutathione Levels and Drug Metabolism Relative to Age." July 1, 1979 - November 31, 1982.

28. Public Health Service Grant for $97,741 entitled "Childhood Lead, Pyrimidines and Metabolic Debris." April 1, 1980 - March 31, 1983. Associate Investigator. Dr. Carol Angle - Principal Investigator.

29. American Heart Association Nebraska Affiliate Grant-in-Aid for $7000, entitled "Hemodynamic Properties of 6'-Hydroxycinchonine," July 1, 1980 - June 30, 1981.

30. University of Nebraska Medical Center Seed Grant of $1618 for a project entitled "Intestinal Tract as the Target Organ for TCDD Toxicity," July 1, 1980 - June 30, 1981.

31. University of Nebraska Medical Center Seed Grant of $5000 for a project entitled "Effects of Dilantin on Estrogen Metabolism," July 1, 1981 - June 30, 1982. Dr. H. Lemon - Principal Investigator.

32. State of Nebraska Cancer Research Grant for $30,500 entitled "Cancer and Aging: Role of Glutathione and its Metabolism," July 1, 1982 - June 30, 1983.

33. Public Health Service Grant for $119,290 entitled "Lead and the Red Cell Membrane." July 1, 1983 - June 30, 1986. Co-investigator. Dr. Carol Angle - Principal Investigator.

34. American Heart Association (Nebraska Affiliate) Grant for $23,821 entitled "Lipid Peroxidation: Cause of Myocardial Toxicity to TCDD." July 1, 1983 - June 30, 1985.

35. State of Nebraska Research Grant for $31,911 entitled "Cancer and Aging: Roles of Glutathione and DNA Damage." July 1, 1983 - June 30, 1984.

36. March of Dimes Birth Defects Foundation for $50,000 entitled "Role of Lipid Peroxidation in TCDD-induced Testicular Atrophy." December 1, 1983 - November 30, 1985.

37. Ayerst Laboratories contract for $31,800 entitled "Efficiency of Betacor in Mild-to-Moderate Hypertension (One Step Therapy)." October 1984 - March, 1985.

38. Ayerst Laboratories contract for $31,800 entitled "Efficiency of Betacor in Mild-to-Moderate Hypertension (Two Step Therapy, Post-Thiazide)." October 1984 - March, 1985.

39. National Cancer Institute Laboratory Cancer Research Support (CORE) Grant, 1984-86. Co-Investigator. Dr. E. Bresnick, Principal Investigator.

40. March of Dimes Birth Defects Foundation for $40,000, entitled "Mechanism of TCDD-Induced Testicular Atrophy." December 1, 1985 - November 30, 1987.

41. National Institute of Environmental Health Sciences Area Grant for $50,000, entitled "Free Radicals and Iron in TCDD-Induced Lipid Peroxidation." July 1, 1987 - April 30, 1990.

42. National Institute of Environmental Health Sciences Sabbatical Award for $28,336 for September 1, 1987 - June 30, 1988.

43. American Aging Association, Inc. grant of $500, to support a study entitled "DNA Single Strand Breaks in Peripheral Lymphocytes of Human Subjects as a Function of Age." February 1, 1989 - January 30, 1990. Co-Investigator - Dr. T. Lawson.

44. Health Future Foundation Grant of $5000, to support a study entitled "Macrophage Activation by TCDD." December 1, 1989 - November 30, 1990.

45. William Randolph Hearst Foundation Grant of $30,000, to establish a graduate fellowship. December, 1989.

46. Air Force Office of Scientific Research Grant for $288,897 entitled "Production of Reactive Oxygen Species by Polyhalogenated Cyclic Hydrocarbons (PCH)." June 15, 1990 - June 14, 1993.

47. Ciba-Geigy Grant of $2500 for support of Graduate Students, March, 1990.

48. Smith-Kline-Beecham Grant of $32,660 for support of graduate student George Baker. September, 1990.

49. U.S. Army Medical Research and Development Command Grant for $61,869 entitled "Specific Mechanism-Based Glycosidase Inhibitors as Chemoprotectants Against Ricin Toxicity." June, 1991 - May, 1992.

50. Creighton University BRSG for $2,000 with graduate student Dan Muldoon for a project entitled "Potential Chemoprotectants Agains Ricin Toxicity." June, 1991 - May, 1992.

51. Ciba-Geigy grant of $2,500 for support of the computer laboratory, February, 1992.

52. State of Nebraska Department of Health grant for $59,902 for a project entitled "Smokeless Tobacco: Macrophage Activation and Cytotoxicity." July, 1992 - June, 1994.

53. Health Future Foundation grant of $10,000 to support a study entitled "Production of Reactive Oxygen Species by Cadium and Chromium." July 1, 1993 - June 30, 1994.

54. California Aging Research Institute, Inc. grant of $4,500 to support a study entitled "Age-Related Oxidative Damage in the Retina." October, 1993 - March, 1996.

55. Air Force Office of Scientific Research grant for $321,732 entitled "Mechanisms associated with the toxicity of polyhalogenated cyclic hydrocarbons and heavy metals." November 1, 1993 - October 31, 1996.

56. State of Nebraska Department of Health grant for $151,004 entitled "Smokeless tobacco, reactive oxygen species, oral cancer and collagen synthesis." Dr. M. Bagchi - Principal Investigator. October 1, 1994 - July 1, 1996.

57. Procter & Gamble research grant for $24,998 entitled "Restraint stress, diet, and chemically induced oxidative stress in rats, and protective ability of bismuth subsalicylate (BSS)." Dr. D. Bagchi - Principal Investigator. January 1, 1996 - September 30, 1996.

58. Air Force Office of Scientific Research grant for $339,097 entitled "Common pathways in the toxicity of structurally diverse xenobiotics." November 1, 1996 - October 31, 1999.

59. NACDS Education Foundation grant for $25,000 for a project entitled "A certificate program in diabetes care for pharmacists." Dr. Ken Keefner - Principal Investigator. September, 1997 - July, 1998.

60. NIEHS grant for $101,243 for a project entitled "TCDD-induced oxidative stress in tissues of rats." Dr. Ezdihar Hassoun - Principal Investigator, Dr. S.J. Stohs - Co-Investigator. April, 1998 - March, 1999.

61. NIH grant for $70,000 for a project entitled “Helicobacter pylori, oxidative stress and gastric injury”. April, 1998 - March, 2001.

62. Institute for the Advancement of Community Pharmacy to create "an asynchronous web-based Doctor of Pharmacy Pathway at Creighton University". July 1, 2000 - June 30, 2003, $1 million.

63. Support for a web-based Doctor of Pharmacy pathway at Creighton University. July 1, 2000 – June 30, 2002: ShopKo - $10,000; Walgreen Corporation - $50,000; J.M. Long Foundation - $50,000; Eckerd Corporation - $10,000; AstraZeneca - $1,000; BD Pharmaceutical Corp. - $10,000; CVS Corporation - $25,000.

64. Research grant from AdvoCare International for $95,435 for a project entitled "Effects of long term chronic exposure to MNS orange on serum chemistry and histopathology in mice." Dr. S.D. Ray – principal investigator, Dr. S.J. Stohs – co-principal investigator. July, 2001 - June, 2003.

65. Research grant from AdvoCare International for $5,000 for a project entitled "Quantitation of ephedra and caffeine in MNS Orange dietary supplement." Dr. Alekha Dash – principal investigator, Dr. S.J. Stohs – co-principal investigator. September, 2001 - June, 2003.

66. Research grant from InterHealth Nutraceuticals Inc. for $20,000 for a project entitled "Determination of testicular atrophy (lipid peroxidation, physical observations and histopathology) in rats following supplementation with Super CitriMax. Dr. S.E. Ohia – principal investigator, Dr. S.J. Stohs – co-principal investigator. January, 2002 - December, 2002.

67. Research grant from the Health Future Foundation for $850,000 for the establishment of a Toxicology Center. Dr. S.J. Stohs – principal investigator, Dr. S.E. Ohia – co-principal investigator, Dr. D. Bagchi – co-principal investigator. July, 2002 - June, 2005.

68. Research grant from InterHealth Nutraceuticals Inc. for $50,000 for a project entitled "ChromeMate 90-day safety study." Dr. Michael Shara – principal investigator, Dr. S.J. Stohs – co-principal investigator. January, 2002 - September, 2003.

69. Over $800,000 in research grants funded by AdvoCare International between 2003 – 2014 for various studies in animals and human subjects on the efficacy and safety of selected AdvoCare products. Dr. S. J. Stohs served as Co-principal investigator on these studies.

70. Research grant from Nutratech Inc. for $22,000 for "A comparative effectiveness study evaluating changes in resting metabolic rate associated with four different nutritional supplements in human subjects." Dr. S. J. Stohs Co-principal investigator with Dr. Gil Kaats, Dr. Harry Preuss-Co-Investigator, June, 2010 – July, 2011.

Updated 04-03-16

EXHIBIT 3

COMMENTARY ON THE REPORT OF DR. SIDNEY J. STOHS CONCERNING THE HEALTH CLAIMS FOR NTX, A PRODUCT COMPOSED OF GLYCYRRHIZIN AND MANNITOL, IN CONJUNCTION WITH ALCOHOL CONSUMPTION

Harry G. Preuss MD, MACN, CNS
Professor of Biochemistry, Medicine, Physiology, and Pathology
Georgetown University Medical Center
Washington, DC 20057

SOURCES USED IN ADDITION TO THE STOHS REPORT

MATERIAL PROVIDED BY COMPANY
PATENT (REF 14)
ADDITIONAL REFERENCES (102-105)

INTRODUCTION

The excellent, extensive report of Dr Sidney J Stohs was the primary basis for my commentaries. I found his report to be quite reasonable and complete in covering the safety and efficacy of the NTX product that is intended to prevent and/or ameliorate the adverse effects of alcohol consumption. In my account, I take highlights from the Stohs' report that were most meaningful to me in making my conclusions.

Previous evidence indicates that the major elements of NTX, namely glycyrrhizin and mannitol individually and combined, favorably decrease reactive oxygen species (ROS) and metabolites, lipid peroxidation (MDA formation) as well as carbonyl protein formation secondary to alcohol-induced production, while positively increasing the levels of the endogenous antioxidant reduced glutathione (GSH)[14,16-49]. In other words, these elements, alone or together, have the ability to lessen hepatic damage from alcohol. In addition, mannitol being an osmotic diu-

retic would lessen the alcohol challenge in a secondary manner by allowing for more rapid renal excretion of the consumed liquid – thus lessening the alcohol challenge[105]. Accordingly, data obtained from the patent[14] indicates that the two elements together have additive effects, and in some parameters studied, even synergistic tendencies.

The Stohs' report states that the patent for NTX points out that glycyrrhizin is used at a concentration of 0.05-0.3 % while mannitol is used in the range of 0.5-3.0 %[14]. Someone consuming 60 ml of an alcoholic beverage (4 shots) containing NTX, would consume in the range of 30-180 mg of glycyrrhizin and 300 mg-1.80 grams of mannitol. For the individual consuming 60 ml of an alcoholic beverage (4 shots) containing NTX, he/she would consume 30-180 mg of glycyrrhizin and 300 mg-1.80 grams of mannitol. The dose of glycyrrhizin would be theoretically lessened by the presence of an osmotic diuretic like mannitol[105]. Long-term experiences using intravenous levels of glycyrrhizin at daily doses of 200 mg without major complications would suggest that the NTX concentration taken orally is safe[98,103].

BACKGROUND

[REFERENCES 1-19]

It is generally recognized that excess chronic alcohol consumption is frequently associated with severe liver perturbations and is quite commom[1-19]. Alcoholic liver disease is composed of various histological stages -- from hepatic fat accumulation to more advanced stages such as alcoholic steatohepatitis, cirrhosis, hepatocellular carcinoma and liver failure [3,4]. A typical pathological progression includes: metabolism of

alcohol to very toxic acetaldehyde along with a variety of free radical species, creation of harmful reactive oxygen (ROS) and nitrogen species with resulting oxidative stress, discharge of inflammatory cytokines such as tumor necrosis factor-alpha (TNF-α) and interleukin-6 (IL-6), deviant lipid metabolism, DNA damage, and ultimately cell necrosis with general systemic malfunctions[3-9].

The status of hepatic health can be assessed by numerous so called biomarkers. Biomarkers indicating disturbed hepatic function include measurements of the blood serum levels of the enzymes such as alanine aminotransferase (ALT), aspartate aminotransferase (AST), gamma-glutamyltransferase (GGT) and alkaline phosphatase (ALP). Importantly, elevated circulating levels of these enzymes are found when the liver is injured from excess alcohol intake and are important biomarkers of the health status of the liver. On the positive side, reduced serum levels of these markers occur as the liver begins to repair[8-12].

In addition to enzymes, other established markers signifying the status of hepatic function are available. For example, the hepatic metabolism of alcohol leads to excess production of tissue-injuring free radicals and reactive oxygen species (ROS) as mentioned above. Markers of oxidative stress and oxidative tissue damage include reactive oxygen species (ROS) production, the lipid metabolite malondialdehyde (MDA), protein carbonyl formation, and DNA damage. Also, reduced glutathione (GSH) content is a key intracellular antioxidant and chemoprotectant in human tissues, because a diminution in GSH is associated

with augmented oxidative stress as occurs in the case of alcoholic liver disease[8-12]. Accordingly, GSH content is an important marker of the status of ROS and free radicals.

Because of its proclivity, there is a vital need to develop safer strategies to ameliorate the effects of chronic alcohol overindulgence and to develop strategies that reduce alcohol-associated morbidity and mortality. NTX is a patented product composed of the primary ingredients glycyrrhizin and mannitol that act effectively when combined. Numerous studies in humans and animals have demonstrated the hepatic protective effects of NTX as well as its individual components during acute and chronic alcohol consumption. Importantly, the safety of the ingredients in NTX is well established.

HEALTH CLAIMS FOR NTX

1. PROVIDES ANTIOXIDANT AND ANTI INFLAMATORY SUPPORT

References [14, 16-49]

A plethora of animal studies have shown that licorice extract and mannitol alone favorably decrease reactive oxygen species (ROS) and metabolites, lipid peroxidation (MDA formation) as well as carbonyl protein formation secondary to alcohol-induced production, while positively increasing the levels of the endogenous antioxidant reduced glutathione (GSH)[14,16-49]. Many of these findings with glycyrrhizin and mannitol have been corroborated in clinical studies [15-17,45-47]. In addition, NTX containing both ingredients decreases the alcohol-induced DNA damage in human peripheral lymphocytes[16]. NTX

also enhances the levels of the enzymes catalase, GPX and SOD that decompose ROS[14] and, in turn, protects hepatocytes from the damaging influences of ROS. Worth reemphasizing, these findings emanate from over 30 published animal, *in vitro*, and clinical studies that confirm the antioxidant and anti-inflammatory properties of the major of individual components of NTX --glycyrrhizin and mannitol as well as NTX itself.

2. HELPS PROTECT AGAINST OXIDATIVE DAMAGE TO THE LIVER.

References [14-16,19,30,35,36,38-44,50-69]

A multitude of published human studies and animal studies have revealed that NTX and a major active constituent (glycyrrhizin) provide a shield against oxidative injury to the liver. No doubt this is due, at least in part, to overcoming primary mechanisms behind alcohol toxicity and liver disease, i.e., oxidative stress and damage[14,-16,19,38-44,50-69] .

A meta-analysis of 12 randomized controlled trials summarizes the ability of a glycyrrhizin product to ameliorate liver dysfunctions in 838 patients with alcoholic liver disease[53]. Because the study found that glycyrrhizin significantly decreases serum ALT and AST levels, the authors concluded that the glycyrrhizin product can significantly improve liver function in alcoholic liver disease[53].

Similar findings occurred when studies examined the combination of glycyrrhizin with mannitol (NTX). A randomized, double-blind, placebo-controlled clinical trial involving human subjects reported that

NTX provided significant liver protection during 12 days of alcohol consumption as evidenced by decreases in the biomarkers of liver toxicity ALT, AST, GGT and ALP[15]. A second randomized, double-blind, placebo-controlled cross-over clinical trial was conducted in which all participants received alcohol with and without NTX[16]. Consumption of alcohol alone caused the following: increased serum ROS and its metabolites, decreased serum GSH, and elevations in MDA, protein carbonyl, and DNA damage in peripheral lymphocytes. However, consuming the alcohol with NTX significantly reduced levels of ROS and several oxidative markers -- demonstrating the tissue protective effects of NTX.

3. HELPS MAINTAIN NORMAL LIVER ENZYME PRODUCTION AND FUNCTION

References [14-16,19,30-34,38,54-67]

Several published human, animal and cell culture studies have discovered that NTX and its primary active constituents glycyrrhizin and mannitol will permit normalization or, at least, near-normalization of a wide range of liver enzymes. These include ALT, AST, GGT, ALP, SOD, GPX and catalase. In addition, they have the ability to ameliorate alcohol-induced inflammation and creation of products signifying oxidative tissue damage. The latter include ROS, carbonyl protein and MDA. Therefore, glycyrrhizin and mannitol singly and in combination protect the liver, and support and facilitate normal liver function in the presence of many challenges including alcohol.

Glycyrrhizin has been shown to reduce, at least to 35%, serum ALT and AST in patients with chronic hepatitis[54-67]. The results depended upon duration of glycyrrhizin administration[54].

A combination of glycyrrhizin and mannitol (NTX) in a randomized, double-blind, placebo-controlled clinical trial involving 12 human subjects who received alcohol daily for 12 days with or without NTX was carried out. When NTX was co-administered with alcohol, it provided significant decreases and normalization in the examined biomarkers of liver toxicity ALT, AST, GGT and ALP[15,16]. Accordingly, NTX overcame to some extent alcohol toxicity and severe liver dysfunction. A second randomized, double-blind, placebo-controlled cross-over clinical trial involving human 31 subjects was conducted whereby all participants received a single dose of alcohol with and without NTX[16]. Co-consumption of alcohol with NTX significantly reduced the levels of ROS to facilitate development of normal liver enzyme circulating concentrations.

4. SUPPORT NORMAL LIVER DEFENSES AND REGENERATIVE MECHANISM

References [14-19,21,22,53,68,69]

Almost 50 published human clinical studies and a wide variety on animal studies have demonstrated that NTX and its individual components glycyrrhizin and mannitol support normal defense mechanisms against alcohol and other hepatotoxins, allowing normal function and regeneration of the liver.

A published meta-analysis of 12 randomized controlled trials (RCTs) has summarized the effects of a glycyrrhizin product on liver function in 838 patients with alcoholic liver disease[53]. The analysis showed that glycyrrhizin significantly decreased serum ALT and AST levels, and the authors concluded that the glycyrrhizin product significantly improved liver function in alcoholic liver disease[53].

A study has examined the beneficial effects of a glycyrrhizin product on alcohol-induced fibrosis in rats[21]. Pathological liver fibrosis was observed when rats were treated daily with alcohol for 16 weeks. Fibrosis was assessed and demonstrated by measuring serum levels of hyaluronic acid, laminin, procollagen III and collagen type IV as well as examining histopathology. All indices of fibrosis were significantly decreased in rats co-administered the glycyrrhizin product, thus demonstrating that the glycyrrhizin exhibits tissue protective effects and supports normal liver function[21].

A double blind, comparative, cross-over clinical trial was conducted which examined the effects of alcohol on blood levels of ROS in the absence and presence of co-administered NTX[17]. The results demonstrated that NTX significantly decreased the alcohol-induced generation of ROS and ROS metabolites, and decreased serum lipid peroxidation product MDA, while increasing serum levels of the endogenous antioxidant GSH. NTX administration with alcohol also significantly decreased

serum protein carbonyl levels, which is another marker of alcohol-induced oxidative stress[17]. Thus, NTX co-administration with alcohol decreased oxidative tissue damage and supported normal liver function.

5. REDUCES THE RISK OF LIVER DISEASES INCLUDING FIBROSIS AND CIRRHOSIS

References [14-16,19,21,22,50-53,54-70,73-75]

Several clinical trials and laboratory studies have establish that the individual components glycyrrhizin and mannitol alone and combined in NTX support normal defense mechanisms and ameliorate alcohol liver diseases lessening the potential fibrosis and cirrhosis, thereby providing healthier function and allowing the potential for hepatic regeneration.

Magnesium isoglycyrrhizinate is a magnesium salt form of glycyrrhizin that improves hepatic function in humans with alcoholic liver[70], disease, chronic hepatitis[71,72], and cirrhosis[73]. This was revealed by decreases in the circulating levels of ALT, AST and total bilirubin. A meta-analysis summarized the ability of a glycyrrhizin to influence liver function in 838 patients with alcoholic liver disease. Data was obtained from 12 randomized controlled trials (RCTs)[53]. The authors concluded that a glycyrrhizin product significantly improved liver function in alcoholic liver disease, because administration markedly decreased serum ALT and AST levels[53].

In a randomized, double-blind, placebo-controlled cross-over clinical trial, it was found that NTX provides significant hepatic protection during 12 days of alcohol consumption when compared to receiving only alcohol. Decreases in the hepatic enzyme biomarkers of liver toxicity ALT, AST, GGT and ALP provided the evidence[15].

A different randomized, double-blind, placebo-controlled cross-over clinical trial involving human 31 subjects was conducted in which a single dose alcohol with and without NTX was given. Duration of washout was one week between cross-over treatments[16]. Alcohol increased circulating ROS and ROS metabolites, lowered serum GSH, elevated MDA, raised protein carbonyl, and increased DNA damage in peripheral lymphocytes. However, consumption of alcohol with NTX significantly lowered concentrations of ROS and all the oxidative markers and increased serum GSH. The results indicated that NTX may "be effective in reducing alcohol-induced pathophysiological changes"[16].

6. AMELIORATES THE SYMPTOMS ASSOCIATED WITH LIVER DISEASE INCLUDING FIBROSIS AND CIRRHOSIS

REFERENCES [14-16,19,21,22,34,50-67,68,69,70-74]

A number of clinical investigations and laboratory studies have shown that NTX and its individual components glycyrrhizin and mannitol support normal defense mechanisms and ameliorate liver diseases including fibrosis and cirrhosis, thereby facilitating improved function and improved regeneration of the liver.

Glycyrrhizin has been found in a number of clinical studies to significantly reduce and normalize serum ALT and AST in patients with chronic hepatitis[54-67].

A meta-analysis assessing liver function in 838 patients with alcoholic liver disease reported the influence of a glycyrrhizin product[53]. Data were derived from 12 randomized controlled trials (RCTs)[53]. Glycyrrhizin administration significantly lowered circulating ALT and AST concentrations. The investigators reported that the glycyrrhizin product significantly made the symptoms better in the alcoholics subjects [53].

Laboratory studies involving animals have corroborated that NTX provides significant protection against alcohol-induced oxidative hepatic damage exemplified by lower circulating levels of ALT, AST, GGT and ALP[14,19]. Oxidative hepatic cellular damage ultimately causes hepatitis, fibrosis and cirrhosis. The combination of glycyrrhizin and mannitol, better than either one alone, ameliorated alcohol-induced presence of reactive oxygen species (ROS) by enhancing the activity level of the enzymes catalase, GPX and SOD that decompose tissue damaging ROS[14], leading to improved liver function. Also, consumption of mannitol and glycyrrhizin (NTX) contributed to healthy functioning of the liver by preventing alcohol-induced depletion of endogenous GSH levels [14].

7, HELPS MAINTAIN NORMAL RENAL FUNCTIONS

References [14-16,19-22,30-35,38,45-54,67-69]

Several laboratory and clinical studies have verified the ability of NTX and its constituents to protect the liver exposed to excess acid challenge acutely and chronically [14-16,19-22,30-35,38,45-54,67-69]. Mannitol , the second major component of NTX has been shown to improve blood flow, contain antioxidant and free radical scavenging properties, and possess anti-inflammatory and antioxidant properties in tissue baths to protect renal functions prior to transplant[46,47]. Similarly, mannitol showed anti-inflammatory and antioxidant activity in rodents after traumatic brain injury, whereby it decreased production of MDA and improved levels of the antioxidant enzymes catalase and GPx[49].

In respect to the workings of glycyrrhizinate alone, a meta-analysis involving 24 randomized control trials examining 3201 patients with chronic hepatitis was published[53]. Diammonium glycyrrhizinate significantly lowered circulating ALT and total bilirubin, and lessened fibrosis, therefore supporting normal liver function.

A meta-analysis summarized the effects of a glycyrrhizin product on liver function in 838 patients with alcoholic liver disease involving 12 randomized controlled trials (RCTs)[53]. Glycyrrhizin administration significantly decreased serum ALT and AST levels. The authors concluded that the glycyrrhizin product significantly improved liver function in alcoholic liver disease[53].

The co-administration of NTX with alcohol significantly lowers and tends to normalize the enzyme biomarkers of liver toxicity -- ALT,

AST, GGT and ALP[15], supporting the hepatoprotective effects of NTX. For example, a randomized, double-blind, placebo-controlled cross-over clinical trial involving 12 human subjects received alcohol daily for 12 days with or without NTX. NTX decreased biomarkers indicating toxicity and revealed that NTX helped maintain normal hepatic function.

In a second clinical trial involving 31 subjects, all participants received a single dose of alcohol with and without NTX[16]. Alcohol by itself elevated circulating levels of ROS and ROS metabolites, lowered serum GSH, increased MDA, raised protein carbonyl, and increased DNA damage in peripheral lymphocytes. When NTX was added to the alcohol challenge, the combination significantly reduced ROS concentrations and all other oxidative markers. The results indicated that NTX may "be effective in reducing alcohol-induced pathophysiological changes"[16], with the distinct possibility of preserving normal liver function.

8. HELPS PROTECT DNA FROM ALCOHOL-INDUCED DAMAGE

9. REDUCES ALCOHOL-INDUCED DNA DAMAGE

REFERENCES [16,38,76-94]

The influence of excess alcohol challenge contributes to the production of oxidative damage to DNA that creates strand breaks and fragmentation[76, 77]. ROS can also activate or repress epigenetic elements as chromatin remodeling, micro-RNAs, DNA (de)methylation and histone modification that affect gene expression and has the potential to bring about several liver disorders[77,78]. In addition, alcohol can form adducts

with DNA, inhibiting the formation of various proteins essential for healthy hepatic function[79,80]. Accordingly, various human, animal and *in vitro* studies have shown that NTX and it principal components glycyrrhizin and mannitol restrain the formation of alcohol-induced DNA damage.

Thirty-one subjects in a randomized, double-blind, placebo-controlled cross-over clinical trial received alcohol with and without NTX[16]. Alcohol challenge resulted in apparent DNA damage in peripheral lymphocytes as determined by the single cell electrophoresis comet assay, the cytokinesis-block micronucleus assay, and 8-hydroxy-2-deoxyguanosine formation. When the alcohol challenge was combined with NTX , a significant reduction in DNA damage occurred. Various studies using human and animal tissues have shown that individually glycyrrhizin and mannitol can prevent oxidative damage to DNA[81-94]. Accordingly, NTX and its major components glycyrrhizin and mannitol have the potential to reduce DNA damage from DNA single and double strand breaks induced by alcohol and other ROS generating systems in liver.

SAFETY

References [15,19,54,97-104]

Licorice and glycyrrhizin are Generally Recognized as Safe (GRAS) for food use in the US.

Over four week, NTX co-administration with alcohol provided significant decreases and normalization in the enzyme biomarkers of liver toxicity ALT, AST, GGT and ALP[15]. Importantly, NTX had essentially no adverse effects on heart rate, blood pressures or respiratory rate, or for that matter any other adverse events as reported in these human subjects[15].

In another trial over 28 days, at no time points did NTX treatment at any of three doses compared to placebo result in significant changes with respect to leukocyte count, erythrocyte count, lymphocyte count, monocyte count, eosinophil count, basophil count, hemoglobin, differential count, blood clotting time, packed cell volume, serum sodium and potassium, plasma AST, ALT, ALP, blood urea nitrogen (BUN), creatinine or total protein. Microscopic examination of the urine sediment of control and NTX treated groups did not reveal the presence of any epithelial casts, bacterial cells, erythrocytes or any other abnormalities at any of the time points over the 28 days of treatment[19]. In another 8 week study involving 39 healthy volunteers, the no effect level for glycyrrhizin was conservatively determined to be 2 mg/kg/day or 160 mg for an 80 kg individual[97].

Several clinical studies using doses up to 200 mg per day, primarily given intravenously were reported[97,102-104]. Most of the studies reported no adverse effects, including a study that continued approximately 10 years. Hypertension with skin rash was reported in one study that lasted for up to 14.5 years and involved daily intravenous injections which

results in much higher blood and tissue levels than achieved by oral administration due to the gastro-intestinal metabolism of glycyrrhizin. Two studies reported headache and three studies reported an increase in blood pressure[99], which cannot be correlated with similar doses given orally.

The subchronic oral toxicity of mannitol was studied in rats that were given approximately 12 grams of mannitol per kg per day for 90 days[101]. This dose would be equivalent to an 80 kg individual consuming about 155 grams of mannitol per day. The authors wrote that mannitol did not produce signs of toxicity. Mannitol is used commonly to produce volume expansion and reperfusion[105].

CURRICULUM VITAE

Harry G. Preuss, M.D., M.A.C.N., C.N.S.

GENERAL INFORMATION

RANK Professor of Biochemistry, Physiology, Medicine, and Pathology

ADDRESS Georgetown University Medical Center
Basic Science Bldg, Room 231 B
4000 Reservoir Rd NW
Washington, D.C. 20057

TELEPHONES

Work:	Home:
Phone (202) 687-1441	(703) 323-7638
Fax: (202) 687-8788	(703) 764-8058
E Mail: preusshg@georgetown.edu	

MARRIED October 8, 1960 - 4 children

MD LICENSE District of Columbia #21388
Pennsylvania 1966-1971

EDUCATION

1945 - 1948 Binghamton West Junior High School
Valedictorian
Mathematics and History Prize

1948 - 1952 Binghamton Central High School
Valedictorian
Mathematics & French Prize

1952 - 1955 Cornell University, New York
Dean's list, 1953, 1954, 1955 - BA received in 1956 after 1 year medical school. Three academic scholarships including New York State Regent's Scholarship for College (competitive)

1955 - 1959 Cornell University Medical School, M.D., 1959
New York State Regent's Scholarship (Medical School-competitive)

TRAINING AND ACADEMIC POSITIONS

1959 - 1960 Internship (Straight Medicine)
under Dr. David E. Rogers, Chairman Dept of Medicine

	Vanderbilt University Hospital, Nashville, TN
1960 - 1962	Resident (Straight Medicine) under Dr. David E. Rogers, Chairman Dept of Medicine Vanderbilt University Hospital, Nashville, TN
1962 - 1964	Fellowship - Renal Physiology under Dr. Robert F. Pitts, chairman Dept of Physiology Cornell University Medical School New York, N.Y.
1964 - 1966	Fellowship Nephrology (Clinical & Research) under Dr. George E. Schreiner, Chief of Nephrology Georgetown University, Washington, D.C.
1966 - 1970	Assistant Professor of Medicine under Dr. Jack Meyers, Chairman Dept of Medicine University of Pittsburgh School of Medicine Pittsburgh, PA,
1970 - 1971	Associate Professor of Medicine (Tenured) under Dr. Jack Meyers, Chairman Dept of Medicine University of Pittsburgh School of Medicine, Pittsburgh, PA,
1971 - 1976	Associate Professor of Medicine & Pathology (Tenured 1976) under Dr. Dudley Jackson, Chairman Dept of Medicine Georgetown University Medical Center, Washington, D.C.
1971 - 1994	Director of Research Renal Division Head, Dr. George E. Schreiner
1974 - 1978	Consultant Lecturer to Nephrology Branch National Naval Medical Center, Bethesda, MD
1976 -	Professor of Medicine & Pathology (Tenured) Georgetown University MedicaL Center, Washington, D.C.
1993-1994	Sabbatical in Molecular Biology under Maurice Burg, Arlyn Garcia-Perez, David Sheikh-Hamad Kidney Laboratory, NHLBI, NIH Bethesda MD
1997	Certified Nutrition Specialist (CNS) designated by Certification Board of Nutrition Specialists, New York, NY.
2000	Professor of Physiology, Georgetown Medical Center (Tenured)

2012	Professor of Biochemistry,Georgetwon Medical Center (Tenured)

JOURNAL ADVISORY EDITORIAL BOARDS or SPECIAL EDITORSHIPS

1977 - 1978	American Journal of Medicine
1978 - 2005	Nephron, S Karger, Basel, Switzerland
1979 - 1982	Nephrology Review
1981	Guest editor, Nephron Festschrift for George E. Schreiner, MD
1982	Guest editor, "Compensatory Renal Growth" Symposium Kidney International
1984 -1986	Series Editor, Nephrology Today Co-Editor, Geriatric Nephrology Editor, Management of Common Problems in Renal Editor, The Clinical Practice of Nephrology
1997-1998	Women's Health Journal--Editorial Advisory Board
1989-2003	Clinical Nephrology, Dustri-Verlag, Germany
1989 -	Geriatric Nephrology and Urology, Klewer Academic Publishers,
1991	Guest Editor for Clinics on Laboratory Evaluation: Renal Function, Electrolytes and Acid-Base Homeostasis Saunders Co, Philadelphia, PA
1992	Guest Editor - Symposium on Nutrition and Diseases of Women published in the Journal of the American College of Nutrition
1992 -	Kidney, Springer-Verlag, New York, NY
1992 -	Journal of the American College of Nutrition, American College of Nutrition, New York, NY
1998-2000	Women's Health Alternative Medicine Report. Mary Ann Liebert, Inc, Larchmont NY.
1999-	Original Internist, Clinton Publications, Rolla, MO
	Research Communications in Pharmacology and Toxicology, PJD Publications LTD, Westbury, NY

2002	Consultant to Arthritis Today, Supplement Guide 200
	Council of Chief Editors of RCPT -- Research Communications in Pharmacology and Therapeutics
	Current Nutrition and Food Science- Editorial Board
2009	Natural Medicine Journal – Editorial Board
2010	International Journal of Green Pharmacy Editorial Board
2010	International Journal of Physiology, Pathophysiology and Pharmacology, Editorial Board

AWARDS, HONORS, POSITIONS HELD

1962 - 1965	NIH Postdoctoral Fellowship
1966-1967	NIH Special Research Fellow
1967 - 1972	Established Investigator, American Heart Association
1968	Interstate Postgraduate Medical Association Research Prize for young investigators
1971	Member, Site Visit Team Cincinnati Veterans Administration Hospital Cincinnati, Ohio Core Research Grant
1972 - 1976	National Kidney Foundation, Washington, DC Peer Review Board
1978 -	Beta Chapter, AOA, Washington, D.C.
1979 - 1981	Clinical Science 3, NIH Study Section (member), Bethesda MD
1981 - 1985	Research Committee, Peer Review, Virginia Chapter of American
1982	Research Task Force, Northern Virginia Chapter American Heart
1983 - 1987	Member, National Advisory Council on Aging, Bethesda, MD Data Planning Committee, NIA Program Committee, NIA
1984	Ad Hoc Member, Biochemistry Study Section N I H, Bethesda, MD

1984 - 1986	Member, Director's Advisory Council NIH (Wyngaarden), Bethesda, MD - NIA Representative
1985 - 1989	American Heart Association, DC Chapter, Research Committee, Peer Review, Washington, DC
1986	Member, NIH Site Visit Team Polycystic Kidney Disease Program Grant Albuquerque, New Mexico
1988 - 1990	AHA, Nation's Capital Affiliate Development Committee
1990 - 1997	Chairman Nephrology-Hypertension Council, Am College of Nutrition
1991 - 1997	ACN - Coordinator Cardiovascular-Nephrology-Hypertension
1992-1993	Elected Board of Directors American College of Nutrition
1993 - 1997	Member of Board Human Kurdish Right Committee, Washington DC
1993 - 1996	American College of Nutrition Secretary-Treasurer Chairman Finance Committee By-Laws Committee
1994	American College of Nutrition Program Committee
1994	ACN representative ILSI meeting: “Sodium and Health”, Washington, DC
1994	American College of Nutrition Representative to ILSI Conference on Sodium: Health and Disease
1995-	Representative of ACN to National Cholesterol Conference at NIH
1995	American College of Nutrition Representative to Partners for Heart Disease and Stroke Prevention. A Vision for Action. sponsored by Assoc of State and Territorial Health Officials, Washington, DC.
1995	Member Advisory Board for Certifying Examination (CBNS)
1995	Chairmen: Washington Welcoming Committee ACN Meeting in

Oct 1995

1995	ACN Representative: ASTHOS meeting on Prevention of
1996 - 1997	ACN, Vice President
1996 -	ACN Representative to the Nutrition and Health Council of America, Georgetown University
1997-1998	President-Elect American College of Nutrition Program Director for 1998 Annual Meeting ACN
1997-	Director of the National Research Council for Health (NRCH) Boise, ID
1997	Selected as laboratory for 1997 Science Teacher Summer Research Fellowship Award -- Douglas Tyson American Society for Clinical Investigation: Committee on Science Education
1997	Nominated for FDA Commissioner by Senators Daschle and Harkin
1997	JACN Advisory Board for Richardson Prize for Research Excellence.
1997-1999	Member of Alternative Medicine Program Advisory Council, NIH. Appointed by Secretary of Health -- Donna Shalala
1997	Invited Participant to National Institute of Aging Conference in Tucson AZ “Micronutrients and Aging”.
1998	Board of Directors -- National Research Council for Health (NRCH)
1998	President American College of Nutrition
1998	Board of Directors, American Preventive Medical Association, Falls Church, VA
1998	Member for the National Cholesterol Education Program Coordinating Committee Meeting. NHLBI. Renaissance Hotel. Washington DC Dec .
1998	Co Chairman ACN Session-- Free Radicals, Apoptosis, and Human Health: Role of Antioxidants

	Invited Lecture: Natural Therapies for Osteoarthritis: Non Drug Invited Lecture: Aging in Relationship to Insulin Resistance in The Cutting Edge of Aging Research in Nutrition Session
1999	Office of Dietary Supplements Advisor Quarterly Conference Calls.
1999 ences,	ACN representative to USNC/IUNS if National Academy of Sci- Institute of Medicine
1999	ACN Representative to Calcium Summit: Developing a public health strategy to insure America's optimal calcium intake. International Trade Center/Ronald Reagan Bldg, Washington DC June 25
1999	Office of Dietary Supplements, NIH, Delegate to Chromium Meeting in November 1999
1999-	Permanent ACN representative to National Cholesterol Education
1999	Invited Member: Nutrition Research Academy
2000 -2002	Chairman of the ACN Council -- "Dietary Supplements, Nutraceuticals, and Functional Foods
2001-2003	Treasurer American Association for Health Freedoms
2001	Fellow of the American Association of Integrative Medicine Diplomate of the College of Physicians Diplomate of the College of Nutrition
2001	Elected the Ninth Master of the American College of Nutrition
2001-2003	Treasurer American Association for Health Freedoms
2002-2003	Elected Board of Directors American College of Nutrition
2003-2004	Nutrition Policy Institute of ACN – President
2002	James Lind Award for excellence in supplement research
2004	Mark Bieber Award of the American College of Nutrition for promoting unity between industry and academia
2004	Advocare Award for Best Research Poster, American College of Nutrition, annual meeting

2004	Member of Expert Panel Diabetes 2020. Report prepared for TSN 109225 Nov 2004 Healthcare.
2006	ACN Charles Ragus Award – Best research paper JACN 2006
2007-	Adjunct Professor, Union Institute and University, Cincinnati Ohio. (Joan Ifland and Shoshona Shinnar
2009	President ACN (second time)
2010	American College of Nutrition Award for outstanding senior investigator in Nutrition.
2011	President ACN (third time)
2011	Chairman, Scientific Advisory Board NutraSpace Internet
2011	Contributing Editor Heart MD Institute
2011	IMBC consultant, Chairman Scientific Advisory Board
2012	Alliance for Natural Health, Scientific and Medical Collaboration Committee Member
2012	CBNS Job Analysis Task Force (member)
2014	Emord Sacred Fire of Libertky Awards – 3 awards Excellence award in Medical Research Excellence award in Integrative Medical Research Excellence award in Nutrition Research
2014	American College Nutrion Presidentail Recognition Award

MEMBERSHIP IN PROFESSIONAL SOCIETIES.

1966 -	American Federation for Clinical Research
1967 -	International Society of Nephrology
1968 -	American Society of Nephrology
1968 - 1982	Central Society for Clinical Research
1969 -	American Society of Physiology

1970 -	Society for Experimental Biology & Medicine
1974 -	American Society for Clinical Investigation
1979 - 1982	New York State Academy of Science
1983 - 1985	American Association for the Advancement of Science
1984 -	American Society of Renal Biochemistry
1985 -	Association of Clinical Scientists
1985 -	American Society of Hypertension
1988 -	Fellow, American College of Nutrition
1999	American Society for Pharmaceutical and Experimental Therapeutics
	Fellow of the Institute for Integrative Medicine
2004	Member North American Association for the Study of Obesity (NAASO)

UNIVERSITY COMMITTEES AND DUTIES

1971 -	Georgetown Representative to Washington VA Research Board
1978 - 1979	Committee to Review Pharmacology Department
1979 - 1980	Chairman, Committee to Review Biochemistry Department
1979 - 1997	Subcommittee on Scientific Merit (IRB) Chairman, 1986 -1997
1979 - 1985	Member, Student's Financial Appeals Board Chairman, 1981 - 1985
1981 - 1982	Member, Search Committee Biochemistry Department Chairman
1981 - 1983	Member, Graduate Committee Department of Pathology
1981 - 1990	Member, Ad Hoc Committee on Teaching Department of Patholo-

	gy
1984 - 1991	Interdepartmental Research Group Georgetown University Medical Center Chairman
1984 - 1986	Animal Welfare Committee
1984 - 1985	Georgetown University Committee on Aging Subcommittee on Research
1984 - 1987	Georgetown University Research Committee (Chairman, 1984 – 1 985) (Vice Chairman, (1985 - 1986)
1985 - 2003	Director, Student's Research Day - GUMC
1986 - 1997	GUMC Institutional Review Board (Vice Chairman)
1987 - 1995	Member, Gertrude Maegwyn-Davis Award Committee
1987 - 1995	Ad Hoc, Student Academic Appeals Committee
1987 - 1988	Dean's Task Force on Incentives for Obtaining Extramural Funds (Chairman)
1997 -2000	JSHS - Judge
1998 -2008	Chairman Institutional Review Board
2002	Co-Director of Nutrition Course at Georgetown with Dr. Eugene Davidson
1998	Pharmacy Committee for IRB
2008	Georgetown External Awards Committee

CONSULTATIONS

1987 - 1988	Expert Witness-Patent Infringement Moduretic Patent Merck, Sharp & Dome vs. Biocraft
1995	Consultant for Ciba-Geigy Pharmaceuticals. Use of Auriculin (Atrial Natriuretic Protein) in Acute Tubular Necrosis.
1995	Ciba Pharmaceuticals, Special Consultant --Obesity and Type II

	Diabetes Mellitus"- Use of Bromocriptine”
1995	Research Project for InterHealth Concord CA
1995	Expert Witness Electromedical Products, Mineral Wells Texas
1996-	Birkmayer Inc, Vienna Austria: Use of NADH in Syndrome X Effects of NADH on Chronic Fatigue Syndrome
	Emords Associates, Washington: DC Role of Fiber in Health
	Medical Products Laboratories, Philadelphia PA --Benzocaine as Local Anesthetic.
	Great Salt Lakes Mineral Corporation, Ogden Utah Toxicity of Armak 1225
	Ciba Pharmaceuticals, Summit NJ, ACE inhibitors and renal protection
	Richardson Laboratories, Boise ID -- Saw Palmetto and Ginkgo Biloba
1997-	Sci-Med Board of Advocare, Inc, Dallas Texas
1998 - 2000	Rexall-Sundown consultant
1998	Consultant to Clinical Trial on the Use of Glucosamine in the Treatment of Osteoarthritis. National Institutes of Health Jan.
1998	Optimum Lifestyle Inc., Mill Valley CA.
1998	Novartis Pharmaceutical. Aminoguanindine.
2000 -2003	Venable Law Firm (Enforma Nutraceuticals)
	Sunny Health Enhancement Center (Taipei and USA) Scientific Advisory Board
2002-2004	Pharmaton (Boeringer-Ingelheim). Representative of SAMe and glucosamine for production of Flexium
2005-	Fuji Chemical. Japan
2006	Manett Law Firm (Shari Lieberman Chitosan)

2006-	Pharmachem, NJ (Phase 2)
	Stop Aging Now, Washington, DC
2008	Sarcona Case in Florida. Witness for defense. Chitosan
2009-2013	Neways International, Scientific Advisory Board
2013-2014	IsaGenix, Scientific Advisory Board
2013-2014	Expert Witness, Pfizer vs. Nutrition 21

LECTURESHIPS, TEACHING, & OTHER ACTIVITIES

1975	Visiting Professor University of Michigan Medical Center Ann Arbor, Michigan
1978	Visiting Professor Loyola University Medical Center, Chicago, IL
1978	Invited Lecturer First International Workshop on Renal Ammoniagenesis, Montreal, Canada
1981	Visiting Professor, St. Louis University School of Medicine St. Louis, MO
1981	Invited Lecturer Second International Workshop on Ammoniagenesis, Athens, Greece
1984	Invited Lecturer Third International Workshop on Ammoniagenesis, Carmel, CA
1985	Visiting Professor, Nagasaki University Medical Center Nagasaki, Japan
1986	Invited Lecturer Biochemistry of Systemic Acid-Base Balance Titisee, Germany
1986	Invited Lecturer 8th Annual European Renal Biochemistry Meeting Dubrovnic, Yugoslavia
1987	Invited Lecturer New York Academy of Medicine

	Geriatric Nephrology Symposium, New York, NY
1987	Faculty (Invited Lectureship) 2nd Annual Meeting The American Society of Hypertension, New York, NY
1987	Invited Lecturer, Session Chairman 4th International Workshop on Ammoniagenesis Cadarache, France
1987	Faculty, Seminar on Geriatric Nephrology Lenox Hill Hospital, New York NY
1988-	Invited Lecture, Seventh Annual St Louis GRECC Symposium: Endocrine Function and Aging
1990	Visiting Professor Loyola University Medical Center
1991	Co-Course Leader PMA Symposium- Hypertension January 1991
1991-1994	Appointed course leader for PMA Symposium on Hypertension to be held October 1991, 1992
1991	Appointed course leader for PMA symposia on Laboratory Evaluation held in December 1991 and 1992
1993	Co-chairman of Symposium on Nutrition and Cardiovascular Diseases and Hypertension - ACN Annual Meeting Chicago, IL
1992	Invited Lecturer-American College of Nutrition. Subject: Lead influence on mentation and the cardiovascular system.
1992	Invited lecturer- Lenox Hill Hospital Exogenous Factors Affecting Blood Pressure
1993	Invited faculty member and speaker Conference on the Inclusion of Women and Minorities in Clinical Research sponsored by PPRR, Georgetown University
1993	Invited speaker "Advances in Perinatal and Pediatric Nutrition" on "Lead Toxicity-Effect on Intellect and Hypertension" Stanford University, Palo Alto CA
1993	Co-chairman of symposium on Nutrition and Cardiovascular Diseases and Hypertension - ACN Annual Meeting, Chicago, IL

1993	Invited Author "Nutrition" for Encyclopedia Americana
1994	Invited Speaker USDA -The Role of Macronutrients in Blood Pressure Regulation
1994	Visiting Professor Lenox Hill Hospital - “Sugar and Hypertension”
1995	Invited speaker Washington Area Micronutrient Club, "Insulin Resistant Disorders"
1995	Co Chairmen: Interaction of Nutrition and Genetics on Chronic Diseases. ACN Meeting in Washington DC Invited speaker Dairy Council. Interaction of Genetics and Nutrition
1995	Invited speaker Expo East Antioxidant conference, Baltimore MD "Effects of chromium on blood pressure and free radical formation (Sept 1995).
1995	Guest speaker Treatment of Hypertension Martinsburg West VA and Patuxant Naval Base MD
1996	Invited speaker Fourth International Conference 0n Geriatric Nephrology and Urology. "Macronutrients and Trace Elements as They Affect Blood Pressure of the Elderly." Toronto Canada (April, 1996)
1996	Invited Speaker, Japanese Society of Urology, Special Lecture "Aspects of Geriatric Nephrology" Nagasaki, Japan (May 1996).
1996	Invited Speaker. Second International Congress on Alternative and
1996	Co-Chairmen Symposium Nutritional Factors Affecting the Glucose-Insulin System: Role in Chronic Diseases and Aging ACN meeting Invited speaker ACN annual Meeting in San Francisco CA: Insulin
1996	Co-Chairmen Symposium Controversies in the Nutritional Management of Chronic Fatigue Syndrome ACN meeting San Francisco CA
1996	Taped Interview on Nutritional and Exogenous Factors Affecting Overall Health Nutrition and Blood Pressure Regulation Preventive Medicine Update, Clinician of the Month (May 1996)
1996	ACN Vice President 1996, President-Elect 1997, President 1998 Vice Chairman Program Committee 1996

1997 Invited speaker to Chiropractors' Meeting, Scottsdale, Arizona July 1997 "Natural means to control blood pressure."

1997 American College for Advancement of Medicine (ACAM)- Invited speaker to Anaheim CA. Harold Harper Lecture "Antioxidants and Hypertension) and workshop on "Role of Antioxidants in Aging."

1998 Invited speaker to Calcutta India. Antioxidants and Stress: Hypertension January, 1998.

1998 Invited lecturer to Chromium Conference in Boston Mass, May 1-2, 1998 Topic: Chromium Effect on BP

1998 Invited Speaker -- Natural Sensations Symposium on Syndrome X May 10, 1998

1998 Invited Speaker "Nutrition and Cancer" and commentator on session "New Biologicals to Treat Cancer, Comprehensive Cancer Care: Integrating Complementary and Alternative Therapies, Washington, DC June 12-14, 1998

1998 Invited Speaker - Meeting Regulatory and Legal Challenges in the Promotion of Dietary Supplements Washington DC Dec 1998.

1998 Invited Speaker: Conference on Cardiovascular Health. Role of Maitake in Lowering Cardiovascular Risk Factors. Expo East, Baltimore MD 1998.

1998 Invited Speaker to Texas Board on Diabetes Mellitus. Natural means to prevent or treat type 2 diabetes.

1998 Invited Speaker to International College for Advancement of Longevity Medicine (InCALM) Reno Nevada. Insulin Resistance in Aging

1998 Invited Speaker to Night of Innovation, ACAM Meeting Phoenix AZ. New Findings Concerning the Clinical Relevance of Maitake Mushroom and Its Extracts.

1999 Invited Speaker to Natural Means to Prevent Aging , Expo West Anaheim CA. Clinical Relevance of Maitake Mushroom in Cancer Treatment.

1999 Three Clinical Conferences via phone satellite on the "Use of glucosamine sulfate in the treatment of osteoarthritis. In: The Emerging Role of Complementary Therapy in the Clinical Setting" National CME/CE Audioconference/Audiocassette Series. Pragmaton, Chicago IL.

1999	Invited Lecturer -- Michigan Pharmacist Association's 2000 Annual Convention and Exposition, Dearborn, Michigan Use of herbs to treat Prostatitis and BPH (Feb 1999)
1999	Invited to write chapter for ILSI: Present Knowledge in Nutrition, 8th Edition (Sodium, Chloride and Potassium)
2000	Invited Speaker 4th Annual International Symposium on Aging Skin Fort Lauderdale FL "The Role of Insulin Resistance in Aging."
2000	Invited speaker -- Modified Foods in the Marketplace, Univ of North Carolina JJB Anderson Chairman
2000	Invited judge 38th National Junior Science and Humanities Symposium-- Paper Competition - Academy of Applied Science 4H Center, Bethesda MD
2000-2001	Consultant to Reader's Digest Book on "Looking after Your Body. An Owners' Guide to Successful Aging." The Philip Leif Group and Reader's Digest Association, Pleasantville, NY, pp 1-416, 2001.
2000	Invited Speaker to symposium on Natural Therapy for Diabetes. University of Guelph "Effects of chromium and other natural substances on glucose-insulin metabolism". Toronto Canada (Sept 2000).
2000	Invitation "Strategies in Internal Medicine and Beyond" Examining the Benefits of Nutraceuticals. Saint Joseph Mercy Hospital, Ann Arbor, MI (Oct 2000).
2000	Invitation to speak at 10th Biennial Meeting of International Society for Free Radical Research. "Effects of a novel grape seed extract and a niacin bound chromium supplement on the lipid profile of hypercholesterolemic patients. Kyoto Japan O 18-4, SFRRI 2000 p 81.
2001	Invited speaker. Expo West Antifungal Action of Oil of Origanum (March)
2001	Invited participant in "Alcohol and Wine in Health and Disease," Palo Alto, CA in April, 2001. Topic: Grape Seed Extract: Effects on Aging and Various Aspects of Syndrome X.
2001 -- (May)	Invited Speaker to Nick Perricone Conference on Aging, San Diego CA "Natural Means to Overcome Syndrome X"

2001 Invited Speaker to ACAM Conference in Nashville TN (May). "Scientific Method to Evaluate Natural Products"

2001. Member Steering Committee for Alternative Medicine Summit. Georgetown University October 2001

2002. Invited Lecturer: First Annual Nutrition Week San Diego "Interesting Nutraceuticals" February

2002. Invited Lecturer to Expo West, Anaheim CA March
Overview of Maitake
Effects of Cernitin on Weight Loss

2002. Invited Lecturer Mini Med School, GUMC March "Interesting Nutraceuticals"

2002. Invited Lecturer to Perricone Conference on Aging. May-June in Chicago, "Chipping Away at Syndrome X"

2002 Invited Lecturer to NABC. Food for Health Conference, University of Minnesota, Minneapolis, Minnesota May 2002

2002 Invited lecturer – training camp of Jacksonville Jaguars " Ephedra and other substances banned by the NFL

2002 Co Chairman session of Am Coll Nutr--Perspectives on Nutraceutical and Functional Foods. San Antonio October

2002 Chairman of session of Am Coll Nutr -- Controversies in Nutrition. Risk/Benefit Ratios of Controversial Supplements. San Antonio (October)

2002. Invited speaker, 2nd ICMAN Conference, Vienna, "Maitake Mushroom and Essential Oils: Immune Enhancers and Antimicrobials" 2nd Icman Conference, Vienna Austria

2003 Invited Speaker to Expo West Anaheim CA "Fraction SX of Maitake"

2003 Invited Keynote Speaker for Japanese Alternative Medicine Society, Tokyo Japan June

2003. Co Chair session on Nutraceutical to Treat Obesity, Nashville TN (October)

FDA Task Force on "labeling," 511 Paint Branch Parkway, College Park Maryland, March 13, 2003

2003 National Academies of Science. Invited Speaker for Food for Health Conference June 2003

2004 Virginia College of Emergency Medicine. Hot Springs, VA 2004 Scientific Assembly "Evaluation of Fluid and Electrolytes (Feb)

2004 Co Chair ACN meeting "Intricate Issues of food and supplement labeling guidelines. (Oct)

2004 Invited Speaker and session co chair World Nutra Conference, San Francisco, November "Chitosan, Hydroxycitric Acid, and Chromium in Weight Management: New Clinical Findings"

2004 Member National Center for Complementary and Alternative Medicine, Special Emphasis Panel -- NIH

2005 Co Chair ACN meeting "Sarcopenia and related issues. Co chair of open session, Kiawah Island, SC Oct 2005

2005 Invited Speaker and session co chair World Nutra Conference, Anaheim, November "Sarcopenia"

2006. Japanese Natural Products Fair - Keynote Speaker, Tokyo Japan, March "Treating the Metabolic Syndrome with Natural Dietary Supplements"

2006 American Oil Chemistry Society, Invited Speaker, Kansas City, KA May 2006 "Influence of monolaurin and essential oils as antimicrobial agents"

2006 World Nutra Co-chair session. Presentation: Chromium, an overview of laboratory and clinical studies. Reno, NV, November.

2006 Caloric Control Council - invited speaker, Carb blockers: Effects and safety of Phase 2. Naples, Florida, November.

2006- NIH Study Section NCCAM

2007 Expo West: The science behind carb blockers. February

2007 Co Chair ACN Meeting, Dietary Supplement Safety. Orlando FL

2007 Invited speaker Webinar Audio Conference: Weight Management. Virgo Publishing, November 15.

2007 A4M Anti Aging Conference -Invited Speaker: Antiaging Nutraceuticals December

2008 Expo West – Invited Speaker - Focus on Maitake SX, Anaheim, CA March

2008 Supply Side East- Invited Speaker -Diabesity - Secaucus, NJ April

2008 IFC- Invited Speaker - Globesity, New Burden for a New Millenium, New Orleans, LA June

2008 American College of Nutrition, President

2008 Co Chair session ACN

2009 American Society of Bariatric Physicians, Charleston SC. Invited for 2 lectures – Analyzing Clinical Studies on Dietary Approaches in Weight Management and The Multiple approach Hypothesis in Weight Management. April

2009 Supply Side East, Secaucus NJ. Invited by Virgo Publishing to speak. Weight Management: The Multiple Approach Hypothesis, April.

2009 IFC- Invited Speaker - The "Multiple Target Hypothesis" in Weight Management. Anaheim, CA, June

2009 ISNFF – Invited Speaker – Weight Loss Supplements, San Francisco, CA Nov

2010 Nutracon, Anaheim CA – Invited Speaker- Carb Blockers, Effectiveness and Safety, March 10, 2010.

2011 Invited speaker Expo West, "Beyond the Metabolic Syndrome" March 2011

2011 Contributing Editor www.heartmdinstitute.com

2011 Chairman Scientific Advisory Board of NutraSpace.com

2012 2012 Tea Symposium Steering Committee - Jeff Blumberg, Director Sept 2012

2012 XVI Congresso Brasileiro de Nutarologia, Sao Paulo, Brazil, Sept 2012, Two presentations -- Niacin-bound Chromium increases life span in Zucker rats and Astaxanthin carotenoid and the rennin-angiotensin system.

2012 CBNS Job Analysis Task Force. (Member)

2012 NHRI Symposium Chicago, IL Oct 20 Invited Speaker "Managing Obesity with Natural Dietary Supplements: Lessons Learned from Clincal Re-

search Studies."

2012 ACN Annual Meeting, Morristown, NJ Nov -- Invited lecture "Strategies for the Prevention of Type 2 Diabetes and moderator for session, "New Frontiers in Diabesity and Nutrition Research."

2013 35th Turkish Endocrine and Metabolism Diseases Congress and Hypophysis Symposium, Antalya, Turkey, May 16-18, 2013. "What is the place of herbal products to treat obesity, what is not?"

2013 ACN Annual Meeting, San Diego, CA Nov -- Invited lecture "Weight Loss Studies: Emphasis on *Garcinia cambogia* "2013.

2014 Chairman – Program Committed ACN Annual Meeting, San Antonio TX October. Moderator symposium on GMO and Metabolonics

2014 Invited panelist to AMAC Healthcare Symposium. Washington DC, Promoting Preventive Health Care

2015 Lecture Harvard Medical School Sept 15, 2015 "Lowering circulating glucose evels that are in the non-diabetic range is important for long-term optimal health." At Proceedings of the 18th International Conference. Chronic Diseases: Bioactive Compounds and Biomarkers.

2015 Initiated into National Academy of Inventors. Sponsored by by Georgetown University

Synthesis and *in Vitro* Antioxidant Activity of Glycyrrhetinic Acid Derivatives Tested with the Cytochrome P450/NADPH System

Mourboul ABLISE,[a,b] Brigitte LEININGER-MULLER,[a] Choi Dal WONG,[a] Gérard SIEST,*[,a] Vincent LOPPINET,[a] and Sophie VISVIKIS[a]

[a] *INSERM Unité 525, Centre du Médicament, Faculté de Pharmacie, Université Henri Poincaré Nancy 1; 54000 Nancy, France: and* [b] *College of Pharmacy, Xinjiang Medical University; 830054-Urumqi, Xinjiang, P. R. China.*
Received May 20, 2004; accepted July 21, 2004

Five glycyrrhetinic acid (Ib) derivatives have been synthesized to try to improve the antioxidant activity. Their *in vitro* antioxidant activities were studied using a cytochrome P450/NADPH reductase system from rat liver microsomes. The generation of microsomal free radicals was followed by oxidation of the DCFH-DA probe, while evaluating the capacity to inhibit reactive oxygen species (ROS) formation. Two hydroxylated derivatives, 18β-olean-12-ene-3β,11α,30-triol (II) and 18β-olean-12-ene-3β,11β,30-triol (IV), exhibited strong antioxidant activities. At a concentration of 1.0 mg/ml, these derivatives inhibited ROS formation by 50% and 51%, respectively. Moreover, two homo- and heterocyclic diene derivatives, 18β-olean-11,13(18)-diene-3β,30-diol (III) and 18β-olean-9(11),12-diene-3β,30-diol (V), were also effective in ROS-scavenging activity (inhibition of 41% and 44% of ROS activity, respectively). In the same conditions, the lead compound (Ib) and the reference vitamin E inhibited ROS activity by 31% and 32%, respectively. Our results suggest that the chemical reduction of the 11-keto and 30-carboxyl groups into hydroxyl function (example, II, IV) can increase the antioxidant activity of Ib significantly. In view of these results, our study represents a further approach to the development of potential therapeutic agents from Ib derivatives for use in pathologic events in which, free radical damage could be involved.

Key words glycyrrhetinic acid derivative; antioxidant activity; cytochrome P450/NADPH reductase

The involvement of free radicals in the pathology of human diseases such as atherosclerosis, cardiovascular diseases, and diabetes, has been recognized by a number of authors.[1—3] Protective therapeutic intervention might include natural or synthetic pharmacologic agents with antioxidant activity.[4] Therapeutic agents with multiple mechanisms of protective action, including antioxidant prophylactic properties, may become valuable in attempts to minimize tissue injury in human disease. This may be helpful in pharmaceutical R&D strategies.[4]

Due to multiple protective actions of a triterpenoid from licorice,[5] we have developed some semisynthetic derivatives of glycyrrhetinic acid (**Ib**), the aglycone of glycyrrhizin (**Ia**) which is a major triterpenoic saponin of licorice, and examined their antioxidant capacity. A derivative of licorice root (*Glycyrrhiza glabra* L.) and its main water-soluble constituent glycyrrhizin (**Ia**), a pentacyclic triterpene derivative of the *beta*-amyrin type (oleanane), has been widely used as an antidote, a food additive, and a folk medicine for generations in Asia and Europe.[6] **Ia** can be hydrolyzed into active aglycone, 18-*beta*-glycyrrhetinic acid (**Ib**). Both **Ia** and **Ib** have been shown to have several beneficial pharmacologic activities, such as antiinflammatory activity,[7] antiulcerative effect,[8] antiviral activity,[9] and antihepatitis effect.[10]

Recently, Zakirov and Abdullaev[11] have demonstrated the effective antioxidant and hypolipidemic properties of ammonium salt of **Ib**. It increases superoxide dismutase (SOD) activity and decreases the concentration of malondialdehyde (MDA) and lowers the cholesterol and triglyceride levels by 51% and 71%, respectively, at a concentration of 25 mg/kg in atherosclerotic and hypercholesterolemic rabbits. As a result, it effectively inhibits the progression of atherosclerotic lesion.[11]

Hye *et al.*[12] reported the protective effects of **Ib** against carbon tetrachloride-induced hepatotoxicity and the possible mechanisms involved in this protection. Shibata *et al.*[13] synthesized some new derivatives of **Ib** which suppressed its pseudoaldosteronism side effects, and Kiso *et al.*[14] demonstrated the effective antiinflammatory properties of those derivatives. Nevertheless, the antioxidant effects of these derivatives have not been systematically reported.

The multiple beneficial effects such as antioxidant, hypolipidemic, anti-inflammatory, and antiatherosclerosis effects of **Ib** point to the possibility of developing new active cardiovascular agents from this structural family. We structurally modified **Ib** and prepared five synthetic derivatives to improve the antioxidant activity. We performed a comparative study of their *in vitro* antioxidant properties in a microsomal free radical-generating system and found significant results with increased antioxidant activity for some. In addition, we carried out a computerized hypolipidemic pharmacophore identification of these derivatives with receptor mapping methods and propose a hypothesis to explain their possible hypolipidemic mechanism of action.[15]

Chemistry All derivatives were prepared by the methods previously described[13] (Fig. 1). Many preparative procedures have also been optimized. Other chemicals were obtained from the usual commercial sources. **Ia** was purified from licorice root and hydrolyzed into **Ib** (step a). We reduced **Ib** into the two stereoisomers **II** and **IV** (step b) with an optimized procedure. Dehydration of triol (**IV**) into diene (steps $c\text{-}_1$, $c\text{-}_2$) was conducted to obtain **V** and **III** in a 3 : 2 ratio. The product **VI** was obtained by a reduction of the mixture **II**+**IV** by catalytic hydrogenation in Pd–C at ambient temperature (step $c\text{-}_3$) and in absolute ethanol presaturated with $NaHCO_3$, while rigorously controlling hydrogen

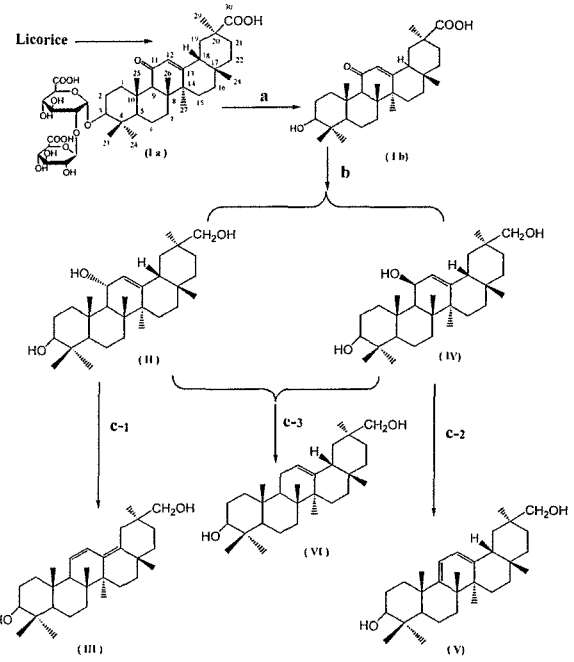

Fig. 1. Synthesis Pathway of Glycyrrhetinic Acid Derivatives

Ia, glycyrrhizin; **Ib**, 3β-hydroxy-11-oxo-18β-olean-12-en-30-oic acid; **II**, 18β-olean-12-ene-3β,11α,30-triol; **III**, 18β-olean-11,13(18)-diene-3β,30-diol; **IV**, 18β-olean-12-ene-3β,11β,30-triol; **V**, 18β-olean-9(11),12-diene-3β,30-diol; **VI**, 18β-olean-12-ene-3β,30-diol.

consumption.

Biochemical The *in vitro* antioxidant activities of these derivatives were tested with a major free radical-generating system, cytochrome P450/NADPH reductase, from rat liver microsomes. The typical antioxidant vitamin E served as a positive control.

The rate of reactive oxygen species (ROS) generation was quantified using the fluorescent probe precursor, 2,7-dichlorofluorescein diacetate (DCFH-DA), a probe that has been utilized extensively for the measurement of microsmal ROS production.[16,17] This assay has been shown to detect the fluorescence associated with the oxidation of DCFH by several reactive intermediates, including superoxide anions, H_2O_2, and hydroxyl radicals in microsomes.[16] Microsomes (rate, 0.5 mg/ml) were preincubated for 15 min with 4 μM of DCFH-DA for deesterification by endogenous esterase in phosphate buffer 50 mM, pH 7.4, at 37 °C. Then the mixture was incubated for an additional 30 min in the presence or absence of NADPH 0.5 mM and a sample (20 μl) using the method described by Choi *et al.*[18] At the end of incubation, fluorescent DCF formation was monitored using an FL 600 Microplate Fluorescence Reader (Bio-Tek, Highland Park, U.S.A.) at an excitation and emission wavelength of 485 and 530 nm, respectively. The rate of ROS generation was linear over the incubation period. A standard curve using DCF 0.01—0.10 μM was prepared and the results are expressed as picomoles of DCF formed per minute per milligram of protein.

The experiment was conducted at least three times. Statistical analysis was performed using one-way ANOVA (SAS software, SAS Institute Inc., NC). A value of $p<0.05$ was considered statistically significant. All biochemical results

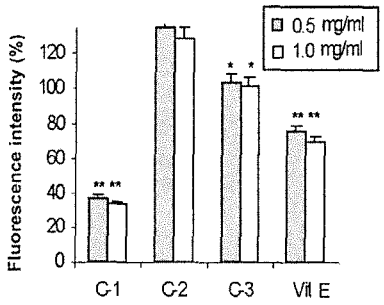

Fig. 2. NADPH-Initiated Microsomal Oxidation of DCFH-DA and Its Modification in the Presence of Vitamin E

The reaction mixture was composed of the microsome suspension (0.5 mg/ml), NADPH-generating system, DCFH-DA and vitamin E. After incubation at 37 °C for 30 min, microsomal oxidation was measured by the methods described. Values are the mean±S.D. of three individual determinations. Asterisks indicate a significant difference from the NADPH control (one-way ANOVA test, SAS software) $*p<0.05$, $**p<0.01$. Control 1 (C1), microsome alone; control 2 (C2), microsome+NADPH; control 3 (C3), microsome+NADPH+DMSO/ethanol; Vit E, vitamine E+NADPH+DMSO/ethanol.

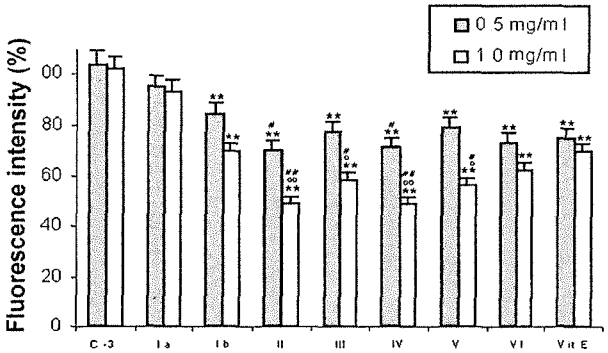

Fig. 3. NADPH-Initiated Microsomal Oxidation of DCFH-DA and Its Modification in the Presence of Glycyrrhetinic Acid Derivatives (**Ia**—**VI**) and Vitamin E (Vit E)

The reaction mixture was composed of the microsome suspension (0.5 mg/ml), NADPH-generating system, DCFH-DA, and the derivatives. After incubation at 37 °C for 30 min, microsomal oxidation was measured. Values are the mean±S.D. of three individual determinations. Asterisks indicate a significant difference from the NADPH control. C3, microsome+NADPH+DMSO/ethanol. * Significant difference *vs.* C3 ($*p<0.05$, $**p<0.01$); ° significant difference *vs.* vitamin E ($\circ p<0.05$, $\circ\circ p<0.01$); # significant difference *vs.* **Ib** ($\#p<0.05$, $\#\#p<0.01$) (one-way ANOVA test with SAS software).

are reported in Figs. 2 and 3.

Results and Discussion

Chemistry We applied a destruction method of aluminum salt with a calculated quantity of NaOH in reaction step b to minimize the rate of the second reaction (dehydratation of triols) and to facilitate the separation of product **II** from **IV** (the two stereoisomers) and from the byproduct aluminum salt. With this method, we achieved good separation of isomer **IV** with high purity with a simple crystallization method in chloroform and then in THF/AcOH. The isomer **II** was purified using the silica gel chromatographic method.

Dehydration of the triol **IV** into a diene (reaction step C-2) allows us to obtain a mixture of **V** and **III** in a 3 : 2 ratio. **III** was purified by recrystallization in absolute ethanol with $NaHCO_3$ under pressure, and **V** was purified by recristallization in chloroform. The separation process was performed using TLC and HPLC methods.

The product **VI** was obtained by reduction of a mixture of **II**+**IV** by catalytic hydrogenation in Pd-C, at ambient temperature and in absolute ethanol presaturated with $NaHCO_3$. It was purified by recrystallisation in ethyl acetate with a yield of 90%.

Biochemistry Samples were subsequently added to the biological oxidative system at a concentration of 0.50 and 1.00 mg/ml. The addition of NADPH to rat liver microsomes initiated DCFH-DA oxidation. This oxidation was elevated more than four-fold in the presence of 0.5 mM of NADPH (428±46 pmol/min/mg protein). At first, the addition of vitamin E (a known ROS scavenger) at an concentration of 1.0 mg/ml to the oxidation system resulted a diminution of DCFH-DA oxidation by 32%, as shown in Fig. 2. Second, the addition of 25 μM of DPI (an inhibitor of flavin oxidoreductase such as NADPH-cytochrome P450 reductase)[19] to the system resulted in suppression of NADPH-dependent electron transfer, and the oxidation of DCFH-DA was inhibited by 85%. These results demonstrate that ROS scavengers and inhibitors of microsomal enzyme can prevent the NADPH-dependent oxidation of DCFH-DA. We used this successful oxidation system to evaluate the NADPH-dependent ROS inhibition properties of our derivatives. We subsequently observed the inhibitory properties of NADPH-generated ROS production by the prepared derivatives. We found that the two hydroxylated derivatives **II** and **IV** have the most potent antioxidant activity. At a concentration of 1.0 mg/ml, they inhibited ROS formation by 50% and 51%, respectively, in the microsomal system. Moreover, two homo- and heterocyclic diene derivatives **III** and **V** inhibited ROS activity by 41% and 44%, respectively. Under the same conditions, the lead compound **Ib** inhibited ROS activity by 31%. The ROS inhibitory capacity of these derivatives increased with increasing concentration. We found that the saponin **Ia** had less antioxidant activity. All the results are shown in Fig. 3. Furthermore, we observed that the addition of an ethanol and DMSO mixture used to solubilize the products decreased the DCFH-DA oxidation levels relative to the control 2.

In the present study, we examined the initial structure–activity relationships of these derivatives by comparing the antioxidant actions monitored by the inhibition of microsomal ROS formation. Compounds **II** and **IV** showed the most intensive activity. The activity of all derivatives was in the decreasing order **IV**≥**II**>**V**>**III**>**VI**>**Ib**>**Ia**. From these results, it can be concluded that chemical reduction of 11-keto and 30-carboxyl functions into alcohol groups can increase the free radical-scavenging activity of the lead compound (**Ib**). However, it is also known that dehydratation of the 11-hydroxyl group gives the homo- and heterocyclic diene derivatives with relatively potent antioxidant activity.

Our findings indicate that the antioxidant property of some synthetic derivatives of **Ib** could represent potential therapeutic activity with multiple protective mechanisms against free radical damage, such as antioxidant, anti-inflammatory, and hypolipidemic properties.

Experimental

Chemistry Melting points were determined on a Kofler apparatus. Reaction courses were routinely monitored using thin-layer chromatography (TLC) on silica gel 60 F254 (Merck) with detection under a 254-nm UV lamp. ^{1}H-NMR spectra were determined in $CDCl_3$ solution with a Bruker DRX-400 (400 MHz) spectrometer and chemical shifts are presented in ppm from internal tetramethylsilane as a standard. Mass spectroanalyses were performed with a quadrupolar spectrometer VG Platform II. HPLC analysis was performed on a Merck L-3000/diode array with a Lichrospher-100 diol column (5 μm, 25 cm). All compounds showed a purity higher than 99% following analytical HPLC. Other analytical parameters including UV (UV Krontron) and IR (with KBr) spectra were also examined.

18β-Glycyrrhetinic Acid. 3β-Hydroxy-11-oxo-18β-olean-12-en-30-oic (Ib) Glycyrrhizin (**Ia**), a diglucuronide saponin of licorice root (*G. glabra*), colorless needless, mp 335 °C, was hydrolyzed to prepare **Ib**, which was used as a starting compound for chemical modification. **Ib**: Colorless needles, yield 70%, mp 296 °C (EtOH). ^{1}H-NMR ($CDCl_3$) δ ppm: 0.83 (3H, s, C-28 H_3), 0.86 (3H, s, C-24 H_3), 1.03 (3H, s, C-26 H_3), 1.15 (3H, s, C-23 H_3), 1.16 (3H, s, C-25 H_3), 1.25 (3H, s, C-29 H_3), 1.39 (3H, s, C-27 H_3), 2.37 (1H, s, C-9 H), 2.81(2H, dt/3.20, 13.6, C-1 H_2), 3.26 (1H, dd/5.80, 10.80, C-3 H), 5.73 (1H, s, C-12 H). IR (KBr) cm^{-1} ν: 3440 (OH), 3046 (C sp^2), 2943 (C sp^3), 1666 (C=O, Cα=Cβ), 1018 (C-3 OH); δ: 1446 (CH_2, α CH_3), 1375 (s CH_3).

18β-Olean-12-ene-3β,11α,30-triol (II) Colorless needles, yield 1%, mp 222—225 °C. ^{1}H-NMR ($CDCl_3$) δ ppm: 0.83 (3H, s, C-28 H_3), 0.86 (3H, s, C-24 H_3), 0.93 (3H, s, C-26 H_3), 1.02 (3H, s, C-25 H_3), 1.03 (3H, s, C-29 H_3), 1.08 (3H, s, C-23 H_3), 1.28 (3H, s, C-27 H_3), 3.26 (1H, dd/5.80, 10.80, C-3 H), 3.55 (2H, AB/-10.96, C-30 H_2), 4.21 (1H or 2H, dd/3.62, 8.16, C-11 H), 5.26 (1H, dd/3.58, C-12 H). Not detected: C-1 H_2, C-9 H_1. IR (KBr) cm^{-1} ν: 3368 (OH), 3061 (C sp^2), 2924 (C sp^3), 1655 (C=C), 1029 (C-3 or 11 OH), δ: 1461 (CH_2, α CH_3), 1375 (s CH_3). MS *m/z* Calcd for $C_{30}H_{50}O_3$: M$^+$ 458.3760. Found: M$^+$ 458.3706. TLC *Rf*=0.19 (ethyl acetate–*n*-hexane, 70 : 30).

18β-Olean-11,13(18)-diene-3β,30-diol (III) Colorless needles, yield 31%, mp 228—230 °C. ^{1}H-NMR ($CDCl_3$) δ ppm: 0.73 (3H, s, C-26 H_3), 0.87 (3H, s, C-25 H_3), 0.87 (3H, s, C-28 H_3), 0.92 (3H, s, C-24 H_3), 0.98 (3H, s, C-29 H_3), 1.07 (3H, s, C-23 H_3), 1.09 (3H, s, C-27 H_3), 3.26 (1H, dd/4.95, 11.28), 3.38 (2H, s, C-30 H_2), 5.56 (1H, d large/10.72, C-12 H), 6.39 (1H or 2H, dd/2.66, 10.36, C-11 H). Not detected: C-1 H_2, C-9 H_1. IR (KBr) cm^{-1} ν: 3353 (OH), 3040 (C sp^2), 2856—2974 (C sp^3), 1637 (C=C), 1022 (C-3 or 11 OH), 926 (C-30 OH), δ: 1478 (CH_2, α CH_3), 1360 (s CH_3). MS *m/z* Calcd for $C_{30}H_{48}O_2$: M$^+$ 440.3654. Found: M$^+$ 440.3658. TLC *Rf*=0.43 (CH_2Cl_2–MeOH, 96 : 4). HPLC t_R=12.8 min.

18β-Olean-12-ene-3β,11β,30-triol (IV) Colorless needles, yield 77%, mp 238—239 °C. ^{1}H-NMR ($CDCl_3$) δ ppm: 0.85 (3H, s, C-28 H_3), 0.89 (3H, s, C-24 H_3), 0.93 (3H, s, C-26 H_3), 1.02 (3H, s, C-25 H_3), 1.13 (3H, s, C-23 H_3), 1.26 (3H, s, C-29 H_3), 1.42 (3H, s, C-27 H_3), 3.26 (1H, dd/5.41, 10.59, C-3 H), 3.55 (2H, AB/-10.77, C-30 H_2), 4.33 (1H or 2H, s large pic, C-11 H), 5.33 (1H, d/3.94, C-12 H). Not detected: C-1 H_2, C-9 H_1. IR (KBr) cm^{-1} ν: 3412 (OH), 2927 (C sp^3), 1634 (C=C), 1022 (C-3 or 11 OH), δ: 1456 (CH_2, α CH_3), 1382 (s CH_3). MS *m/z* Calcd for $C_{30}H_{50}O_3$: M$^+$ 458.3760. Found: M$^+$ 458.3728. TLC *Rf*=0.31 (ethyl acetate–*n*-hexane, 70 : 30).

18β-Olean-9(11),12-diene-3β,30-diol (V) Colorless needles, yield 63%, mp 236 °C. ^{1}H-NMR ($CDCl_3$) δ ppm: 0.83 (3H, s, C-28 H_3), 0.91 (3H, s, C-26 H_3), 0.92 (3H, s, C-24 H_3), 1.03 (3H, s, C-27 H_3), 1.05 (3H, s, C-25 H_3), 1.15 (3H, s, C-23 H_3), 1.21 (3H, s, C-29 H_3), 3.26 (1H, t/5.87, C-3 H), 3.57 (2H, AB/-10.64, C-30 H_2), 5.56 (1H or 2H, dd/5.96, 25.22, C-11 H and C-12 H). Not detected: C-1 H_2, C-9 H_1. IR (KBr) cm^{-1} ν: 3390 (OH), 3038 (C sp^2), 2978—2853 (C sp^3), 1628 (C=C), 1029 (C-3 OH), 985 (C-30 OH), δ: 1449 (CH_2, α CH_3), 1360 (s CH_3). MS *m/z* Calcd for $C_{30}H_{48}O_2$: M$^+$ 440.3654. Found: M$^+$ 440.3663. TLC *Rf*=0.43 (CH_2Cl_2–MeOH, 96 : 4). HPLC t_R=12.2 min.

11-Deoxo-glycyrrhetol (18β-Olean-12-ene-3β,30-diol) (VI) Colorless needles, yield 90%, mp 250—254 °C. ^{1}H-NMR ($CDCl_3$) δ ppm: 0.81 (3H, s, C-28 H_3), 0.85 (3H, s, C-26 H_3), 0.92 (3H, s, C-25 H_3), 0.96 (3H, s, C-24 H_3), 0.98 (3H, s, C-29 H_3), 1.02 (3H, s, C-23 H_3), 1.17 (3H, s, C-27 H_3), 3.25 (1H, dd/4.41, 11.93, C-3 H), 3.54 (2H, AB/-10.82, C-30 H_2), 5.21 (1H, t/3.21, C-12 H). Not detected: C-1 H_2, C-9 H_1, C-11 $H_{1\text{ or }2}$. IR (KBr) cm^{-1} ν: 3268 (OH), 3081 (C sp^2), 2971—2860 (C sp^3), 1691 (C=C), 1022 (C-3 OH), 926 (C-30 OH), δ: 1471—1390 (s CH_3). MS *m/z* Calcd for $C_{30}H_{50}O_2$: M$^+$ 442.3811. Found: M$^+$ 442.3842. TLC *Rf*=0.23 (CH_2Cl_2–MeOH, 96 : 4).

Biochemistry Animals and Microsome Preparation: Male Sprague-Dawley rats (150—180 g, Iffa-Credo, France) were housed in a controlled environment room with a 12-h light/dark photoperiod. The rats were fasted overnight prior to killing. Liver microsomes were prepared by differential centrifugation as previously described.[20] Protein concentrations were determined using the method of Lowry *et al.*[21] with bovine serum albumin as a standard.

Acknowledgment The authors thank Dr. J. C. Ziegler for providing chemical synthesis experience.

Abstract

Alcoholic liver disease (ALD) is a multifaceted disease that is characterized by hepatic steatosis or fat deposition and hepatitis or inflammation. Over the past decade, multiple lines of evidence have emerged on the mechanisms associated with ALD. The key mechanisms identified so far are sensitization to gut-derived endotoxin/lipopolysaccharide resulting in proinflammatory cytokine production and cellular stress due to oxidative processes, contributing to the development and progression of disease. While oxidative stress and inflammatory responses are studied independently in ALD, mechanisms linking these two processes play a major role in pathogenesis of disease. Here we review major players of oxidative stress and inflammation and highlight signaling intermediates regulated by oxidative stress that provokes proinflammatory responses in alcoholic liver disease.

1. Introduction

The pathogenesis of alcoholic liver disease (ALD) is a consequence of chronic alcohol abuse and approximately 44% of the 26,000 deaths from cirrhosis are due to ALD in the United States [1]. Alcoholic hepatitis, the clinical presentation of ALD, remains to be a common life threatening cause of liver failure, especially when it is severe. Chronic alcohol consumption has long been associated with progressive liver disease from steatosis to inflammation, development of hepatic cirrhosis, and the subsequent increased risk of hepatocellular carcinoma. Several studies have attempted to identify the molecular pathways, direct or indirect, affected by alcohol exposure in the liver. These pathways range from oxidative stress, metabolism-related effects, and inflammation to apoptosis. Induction of oxidative stress and activation of the inflammatory cascade are identified as key elements in the pathophysiology of ALD [2]. While these intracellular mechanisms affected by alcohol are studied exclusively, the interplay of signaling molecules between pathways leading to alcoholic liver disease has received less attention. Unraveling these interactions of oxidative stress mediators and inflammatory signaling in the liver will aid in identification of new integrative approaches as it relates to alcoholic liver injury and provide potential new directions to develop therapeutic target intervention. The goal of this concise paper is to first review alcohol-induced reactive oxygen species and oxidative stress generated by alcohol metabolism, endoplasmic reticulum stress, mitochondrial ROS in the liver, protein adduct formation, and autophagy and chaperone function and then to describe stress-mediated activation of receptors, kinases, and transcription factors resulting in proinflammatory signaling in ALD.

2. Classical Mechanisms of Alcoholic Liver Disease

Research done, so far, on the effects of pathophysiological mechanisms of alcoholic liver disease suggests the involvement of two main liver cell types, resident macrophages, or Kupffer cells and hepatocytes. The role of gut-derived endotoxin and liver macrophage activation is clearly established in ALD by Thurman and colleagues [2]. The deleterious effects of alcohol, attributed to its metabolism, primarily occur in hepatocytes [3]. Alcohol metabolism pathway including induction of cytochrome P450 2E1 [3] results in adduct formation and generation of reactive oxygen radicals respectively creating an oxidative microenvironment and damage in the liver [2]. In the currently accepted model of ALD, chronic alcohol induces oxidative stress and sensitization to endotoxin, which activates the CD14/TLR4 pathway and downstream signaling resulting in proinflammatory cytokine production [4]. The proinflammatory cytokines, particularly TNFα, then provoke hepatocellular injury and death by extrinsic, via TNFR1 [5] and intrinsic death pathways [6] leading to ALD. While the role of oxidative stress and macrophage activation, the two main pathophysiological processes affected in ALD, were studied independently in the past, recent studies suggest that these pathways are interconnected in ALD improving our understanding of the disease.

3. Reactive Oxygen Species (ROS) and Alcohol

While activation of inflammatory responses are central to alcoholic liver injury, excessive generation of reactive oxygen species plays an equally significant role in alcohol-induced cellular damage [7]. Alcohol-induced liver disease is associated with a state of "oxidative stress". The metabolism of alcohol by alcohol dehydrogenase [ADH] leads to formation of acetaldehyde. Further, the acetaldehyde is metabolized to acetate by acetaldehyde dehydrogenase [ALDH]. Acetaldehyde, a reactive intermediate has an ability to form adducts with DNA [8, 9]. Whether acute or chronic, alcohol metabolism increases production of acetaldehyde and enhances formation of DNA adducts leading to tissue injury. On the other hand, metabolism of alcohol via cytochrome P4502E1 induces production of reactive oxygen species which facilitates adduct formation, activates stress proteins, induces endoplasmic reticulum stress, and affects lysosomal function and autophagy leading to mitochondrial injury and hepatocellular death.

3.1. Alcohol Metabolism and ROS

Ethanol is primarily metabolized in the liver by oxidative enzymatic pathways. The classical pathway of alcohol metabolism involves enzymatic breakdown of alcohol by the enzyme, alcohol dehydrogenase (ADH) and its subsequent conversion to acetaldehyde and formation of acetate. ADH is predominantly expressed in liver [10] but other tissues like gastric mucosa express ADH and contribute to metabolism of alcohol [10]. Aldehyde dehydrogenase (ALDH) contributes to oxidation of aldehyde intermediates resulting in acetate which is unstable and breaks down to water and carbon dioxide. The second major pathway for ethanol degradation is the microsomal system catalyzed by cytochrome P450 enzymes. The 2E1 isoform of the cytochrome P450 (CYP2E1) system is induced during chronic alcohol consumption. Activation of CYP2E1 leads to ROS generation and highly reactive free radicals including superoxide anions and hydroxyl radicals resulting in oxidative stress and cell death [11]. The role of CYP2E1 in hepatocyte injury has been elucidated using HEPG2 cells overexpressing CYP2E1 [12], CYP2E1 knockout mice, and transgenic mice [13]. Increased oxidative stress from induction of CYP2E1 in vivo sensitizes hepatocytes to LPS and TNFα toxicity [14] and CYP2E1 knock-in mice showed elevated hepatic steatosis and liver injury after alcohol feeding [13]. On the other hand, CYP2E1 knockout mice showed decreased oxidant stress, upregulation of PPARα and were protective to alcohol-induced liver injury. Peroxynitrite, activation of p38 and JNK MAP kinases, and mitochondrial dysfunction are downstream mediators of the CYP2E1-LPS/TNF potentiated hepatotoxicity [15]. Oxidation of ethanol by alcohol dehydrogenase and subsequent metabolism of acetaldehyde results in increased NADH/NAD+ ratio in the cytoplasm and mitochondria [16]. The increase in NADH results in inhibition of mitochondrial β-oxidation and accumulation of intracellular lipids [17]. Alcohol/CYP2E1-mediated ROS has the potential to peroxidize lipids and inhibit mitochondrial and peroxisomal β-oxidation enzymes such as acyl-CoA dehydrogenases, carnitine palmitoyl transferase-1 (CPT-1), and peroxisomal proliferator-inducing pathways, respectively [18]. This disruption leads to increased fatty acids, substrates of these enzymes, and their accumulation resulting in development of hepatic steatosis. Oxidative stress and ROS generation due to alcohol metabolism not only increase accumulation of lipids in hepatocytes but also sensitize the liver to subsequent insults by cytokines.

3.2. Mitochondria and Oxidative Stress

In mitochondria, ROSs are generated as undesirable side products of the oxidative energy metabolism. An excessive and/or sustained increase in ROS production has been implicated in the pathogenesis of ALD, ischemia/reperfusion injury, and other diseases [19]. Oxidative stress induced by alcohol is closely associated with alterations in mitochondrial function resulting in cellular death. Hepatic mitochondria either acutely or chronically exposed to ethanol generate increased levels of reactive oxygen species (ROS) [20]. The induction of mitochondrial dysfunction is also linked to the metabolism of alcohol by CYP2E1 and increased oxidative stress [11]. Primary hepatocytes and rat hepatoma cells when treated with ethanol led to an increase in ROS/RNS and loss of mitochondrial function due to damaged mitochondrial DNA and ribosomes and subsequent inhibition of mitochondrial protein synthesis [21, 22]. Studies have shown that alcohol-induced ROS generation leads to alteration in mitochondrial membrane permeability and transition potential that in turn initiates the release of proapoptotic factors such as cytochrome c [21]. Transition of mitochondrial permeability results in increased caspase-3 activation in hepatocytes and this depends on p38 MAPK activation but is independent of caspase-8 [5]. Various studies show that decreased ATP synthesis accompanied by reduced mitochondrial protein synthesis, inhibition of the oxidative phosphorylation system (OxPhos), and damage to mitochondrial DNA leads to dysfunctional mitochondria and oxidative stress in alcoholic liver disease [23]. Peroxisome proliferator activated receptor gamma (PPARγ)-coactivator 1 alpha (PGC-1α), a transcription coactivator involved in mitochondrial biogenesis, is involved in defenses against ROS by inducing many ROS-mediated detoxifying enzymes. PGC-1 gene expression was lower in hepatic tissues of rats exposed to ethanol [24]. In vitro exposure of hepatoma cells to 500 mM ethanol significantly decreased hepatic SIRT-1; PGC-1α leads to ROS-induced mitochondrial and cellular injury [25]. Certain sirtuins, a family of protein deacetylases, were found to regulate glucose and fat metabolism in mammals [26, 27] and to enhance mitochondrial biogenesis in liver and muscle through PGC-1α and to influence cell survival [28].

Recent studies used an antioxidant peptide targeted to mitochondria to show that altered ROS metabolism facilitates enhanced expression of HIF-1alpha [29], which, in turn, increases TNF-alpha secretion. These findings provide in vivo evidence for the action of mitochondrial ROS on HIF-1alpha activity and demonstrate that changes in mitochondrial function within physiologically tolerable limits can modulate the immune response [29]. These studies suggest that alcohol-induced mitochondrial stress pathways set the stage for proinflammatory cytokine-induced cell death and liver injury.

3.3. Protein Adducts and Lysosomal Dysfunction

Alcohol metabolism and oxidative stress result in the formation of reactive aldehydes such as acetaldehyde, malondialdehyde (MDA), and 4-hydroxy-2-nonenal (HNE) that can bind to proteins to form adducts [30]. In vivo models of chronic alcohol consumption have shown that acetaldehyde, MDA, and HNE adduct formation are increased in various organs including the liver [30]. A strong corelation between 4-HNE adducts and expression of CYP2E1 in patients with ALD was recently shown [31]. Acetaldehyde and MDA react with proteins synergistically to form hybrid protein adducts called malondialdehyde-acetaldehyde (MAA) adducts [32]. Recognition of MAA-adducts by Kupffer cells, endothelial, and stellate cells via the scavenger receptor resulted in upregulation of cytokine and chemokine production and increased expression of adhesion molecules [32]. Circulating antibodies to MAA-adducts were detected in patients with alcoholic hepatitis and cirrhosis and correlated with the severity of liver injury [33]. Chronic alcohol feeding also induces formation of gamma-ketoaldehyde protein adducts in mouse livers [34]. These adducts are formed in a TNFR1/CYP2E1 dependent, but cyclooxygenase-independent manner in mouse liver [34]. Existence of protein adducts during chronic alcohol consumption and their identification in animal models has been challenging, limiting investigation of their precise role in ALD.

Increased ROS and lipid peroxidation rate in microsomal and lysosomal membranes with a simultaneous decrease in the levels of glutathione sulfhydryls and glutathione-S-transferase activity was observed during alcohol exposure [35]. Elevation of cathepsin B in hepatic cytosol fractions, indicating lysosomal leakage, was reported in ethanol-fed rats [36]. Lysosomal leakage was increased in alcohol-fed mice deficient in superoxide dismutase (SOD) indicating that oxidative stress correlated with loss of lysosomal function increased hepatic fat and inflammatory cell infiltration [37]. The exact mechanisms responsible for ethanol-induced changes in lysosomal function are not clear but there is evidence of enhanced lysosomal membrane fragility, which could result from either altered lipid peroxidation, oxidative stress, or both [38]. More recently, degradation of a cell's own cytosolic components in the lysosomes as a protective mechanism against the damaging effects of oxidative stress has been described and is termed autophagy [38]. Alcoholic liver injury is associated with decreased autophagy resulting in accumulation of damaged proteins and liver cell death [38]. Recent studies show that macro-, micro- and chaperone-mediated autophagy is linked to innate and adaptive immune responses [39]. While autophagy acts as an effector and regulator of pattern recognition receptors including TLR4 signaling in macrophages, loss or defective autophagy results in accumulation of cytosolic components and chronic inflammatory responses [40]. How loss of autophagy after chronic alcohol consumption contributes to proinflammatory responses in alcoholic liver disease remains to be investigated.

3.4. Endoplasmic Reticulum (ER) Stress

The unfolded protein response (UPR) is a protective response of the cell also referred to as the ER stress response during pathological conditions. In alcoholic liver disease, increased expression of glucose regulatory protein (GRP)78, GRP94, CHOP, and caspase-12 indicated a UPR/ER stress response [41]. Upregulation and activation of ER-localized transcription factors such as SREBP-1c and SREBP-2 were associated with increased lipid accumulation and induction of fatty liver during chronic alcohol exposure [42]. Another important inducer of ER stress, homocysteine, was increased in alcoholic human subjects leading to hyperhomocysteinemia, also observed in alcohol feeding rodent models [43]. The role of ER stress in triglyceride accumulation and fatty liver comes from studies showing that betaine increases an enzyme, betaine homocysteine methyltransferase (BHMT) and reduces homocysteine levels to inhibit lipid accumulation [43]. Recent studies suggest that ER/UPR stress pathways intersect with innate immune signaling determining the duration and intensity of inflammatory response [44]. Additional mechanistic studies to link ER/UPR stress and innate immune responses as a pathophysiological contributor in ALD are warranted.

3.5. Alcohol, Stress, and Molecular Chaperones

Stress or heat shock proteins (hsps) are ubiquitous and highly conserved proteins, functioning as molecular chaperones, whose expression is induced by oxidative stress stimuli and in response to accumulation of unfolded cellular proteins. Oxidative stress induces heat shock proteins via activation of the heat shock transcription factor (HSF) [45]. Male Wistar rats fed with acute as well as chronic alcohol showed induction of hsp70 in the various regions of the brain and the liver [46, 47]. However, the intensity of induction of hsp70 in the liver, the principal organ of ethanol oxidation, was much lower than the hippocampus or striatal areas of the brain [47]. Hsp90 levels, on the other hand, were increased in cultured rat hepatocytes exposed to acute alcohol [47, 48]. Acute and chronic alcohol treatment of monocytes/macrophages showed alterations in hsp70 and hsp90 mRNA and protein levels based on the length of alcohol exposure [49]. Acute alcohol induces HSF and hsp70, whereas chronic alcohol induces hsp90 but not hsp70 protein, through activation of HSF [49]. Hsp90 functions as a molecular chaperone controlling activity of various kinases and signaling molecules of the LPS signaling pathway such as CD14 [50], IKK [51], and IRAK [52]. Comprehensive studies on the effect of acute and chronic alcohol exposure on chaperone function of hsps in inflammatory responses in the alcoholic liver could provide novel mechanistic insights in ALD.

4. Inflammatory Response and ALD

Extensive studies over the past two decades have identified the importance of macrophage activation in the liver by gut-derived endotoxin after prolonged alcohol consumption [2]. Central to this activation is the sensitization of macrophages due to alcohol exposure and is associated with mechanisms ranging from upregulation and engagement of surface receptors on innate immune cells, intracellular kinases and transcription factors contributing to induction of proinflammatory cytokines.

4.1. Pattern Recognition Receptors, Alcohol, and Immune Cells

Pattern recognition receptors (PRRs) are expressed on liver nonparenchymal and parenchymal cells and function as sensors of microbial danger signals enabling the vertebrate host to initiate an immune response. The complexity of cellular expression of PRRs in the liver provides unique aspects to pathogen recognition and tissue damage in the liver [53]. Toll-like receptors (TLRs) that are membrane associated or endosomal recognize distinct microbial components and activate different signaling pathways by selective utilization of adaptor molecules [54]. TLRs such as TLR4 and TLR2 that detect PAMPs like LPS and lipoproteins, respectively, are located on the cell surface whereas; TLRs such as TLR3, TLR7, and TLR9 that detect viral RNA and DNA are located in the endosome [55]. The pivotal role of TLR4 as well as other TLRs has been extensively studied in alcoholic tissue injury [56–59].

The interaction of oxidative stress and TLR signaling is emerging. TLR4 is capable of inducing ROS leading to oxidative stress [59–61]. Kupffer cells or hepatic macrophages produce reactive oxygen species (ROS) in response to antigenic stimuli and chronic alcohol exposure as well as endotoxin [62, 63]. Alcohol-induced sensitization of macrophages to LPS has been attributed to ROS production [59, 60, 64]. Previous studies from Nagy and colleagues [64, 65] also show that chronic ethanol feeding increases the sensitivity of Kupffer cells to lipopolysaccharide (LPS), leading to increased tumor necrosis factor alpha (TNFα) expression. NADPH oxidase and ROS generation exhibit direct interaction with the TLR4 receptor and activation of down-stream kinases and transcription factors [61]. Studies by Gustot et al. [59] show that oxidative stress regulates TLR 2, 4, 6, and 9 mRNA expression in alcoholic liver. Thus, it appears that TLR mRNA, protein expression, and immune signaling can be strongly influenced by oxidative stress in ALD making these two events dependent on each other and not mutually exclusive. Besides ROS, TLRs also mediate responses to host molecules including intracellular mediators [66]. Amongst the well-characterized DAMPs, high-mobility group box 1 (HMGB1), S100 proteins, hyaluronan, and heat shock protein 60 (hsp60) are known to be recognized by TLR2 and TLR4 [66, 67]. In addition, necrotic or apoptotic cells are also recognized as DAMPs by TLRs [67]. In alcoholic liver injury, apoptotic bodies, generated due to alcohol-induced oxidative stress, could be recognized by DAMPs [68] and contribute to inflammatory responses in the liver.

Activation of TLR4 recruits IRAK-1 to the TLR4 complex via interaction with MyD88 and IRAK-4 [69]. The role of MyD88, the common TLR4 adaptor molecule, was evaluated in a mouse model of alcoholic liver injury [60]. These studies showed that MyD88 knockout mice were highly

susceptible to alcohol-induced fatty liver [60]. While alcohol feeding in TLR4 deficient mice prevented activation of NADPH oxidase, alcohol-fed MyD88 deficient mice showed high NADPH oxidase activity and increased oxidative stress resulting in liver injury [60].

Increasing evidence suggests that downstream signaling components activated by TLRs as well as cytokines and chemokines produced can be regulated by oxidative stress pathways. These interactions of stress pathways leading to inflammation could contribute largely to initiation and perpetuation of alcohol-related injury in the liver. The cross-talk of stress regulated intracellular molecules with TLRs, intracellular kinases and transcription factors resulting in alterations in cytokines/chemokines in ALD are of great importance.

4.2. MAPKs and IKKs

LPS/TLR4-induced ROS activation [61] plays an important role in activation of downstream signaling molecules such as IRAK1/4, TRAF6 leading to activation of MAP kinases and NFκB during chronic alcohol exposure [69]. Mitogen-activated protein kinase [MAPK] signaling cascade plays an essential role in several cellular processes including proliferation, differentiation, and apoptosis. Acute alcohol exposure results in activation of baseline p42/44 MAPK in hepatocytes [70] while chronic alcohol exposure causes potentiation of endotoxin-stimulated p42/44 MAPK, and p38 MAPK signaling in Kupffer cells leading to increased synthesis of TNFα [71, 72]. LPS stimulation of Kupffer cells in vitro exposed to chronic alcohol in vivo exhibited increased p38 activity and decreased JNK activity [71, 73]. Inhibition of p38 activation impaired alcohol-mediated stabilization of TNFα mRNA likely via interaction with tristetraprolin (TTP) [74]. On the other hand, ERK1/2 inhibition did not alter TNFα mRNA stability but affected mRNA transcription in chronic alcohol-exposed macrophages via Egr-1 binding to the promoter [75]. Whether alcohol-induced ROS plays a role in MAPK activation in ALD is not yet determined.

TLR4-induced MyD88-dependent and independent pathways lead to IKK kinase activation resulting in proinflammatory cytokine production [71]. Oxidative stress and ROS-mediated molecular chaperones such as hsp90 are shown to facilitate IKK kinase activity and downstream NFκB nuclear activation [51]. Studies show that chronic alcohol-induced NFκB activation in macrophages is due to increased hsp90 resulting in elevated IKK kinase activity [49]. Inhibition of hsp90 in chronic alcohol-exposed macrophages resulted in decreased IKK kinase activity and NFκB binding suggesting a cross-talk between cellular stress and inflammatory pathways [49].

4.3. Transcription Factors in ALD

The transcription factor NFκB is a ubiquitous transcription factor that can be activated by a large number of extracellular stimuli such as cytokines, chemokines, growth factors, and bacterial or viral products [76]. NFκB activation triggers the induction of inflammatory genes and plays an important role in initiation and progression of alcoholic liver disease [69, 77]. While TLR-mediated activation of NFκB is well established, ROS-induced activation of NFκB occurs but remains poorly understood. Chronic alcohol exposure induces LPS/TLR4-mediated NFκB activation in human monocytes and macrophages contributing to production of proinflammatory cytokine, TNFα [77]. Whether ROS mediates activation of NFκB directly during ALD is unclear. TLR4-induced MyD88-independent signaling leads to activation of IKKε and interferon regulatory factor 3 (IRF3) and downstream Type I IFN activation [78, 79]. Previous studies show that ROS mediates LPS-induced IRF3 activation [80]. Investigators found that IRF3 binds to the TNFα promoter in macrophages after chronic alcohol administration [81] and induces TNFα production. Whether alcohol-induced ROS mediates IRF3 induction to increase proinflammatory cytokines and liver injury needs further investigation.

Alcohol-mediated fatty liver injury is associated with increased expression of genes regulating fatty acid synthesis and suppression of genes involved in fatty acid oxidation [82]. Transcription factors like SREBP and PPARα play a pivotal role in fatty acid metabolism and rodent models as well as in vitro treatment studies with alcohol show downregulation of PPARα mRNA [83]. Further, DNA-binding activity of PPARα is significantly reduced resulting in decreased expression of target genes involved in fatty acid metabolism after alcohol exposure [83]. Decreased PPARα activity was accompanied by increased oxidative stress in the liver resulting in increased sensitization of TNFα-induced liver injury [83].

Another transcription factor, STAT3, in alcoholic liver injury was recently investigated in hepatocyte-specific STAT3 knockout (H-STAT3KO) mice and macrophage/neutrophil-specific STAT3 KO (M/N-STAT3KO) and endothelial STAT3 mice [84]. Compared with wild-type mice, Kupffer cells from alcohol-fed hepatocyte-specific STAT3KO mice produced similar amounts of ROS and hepatic proinflammatory cytokines compared to control mice [85]. On the other hand, Kupffer cells from M/N-STAT3KO mice produced higher ROS and TNFα compared with wild-type controls. These results suggest that STAT3 in hepatocytes promotes ROS production and inflammation whereas myeloid cell STAT3 reduces ROS and hepatic inflammation during alcoholic liver injury [85]. Thus, STAT3 may regulate hepatic inflammatory cytokines via ROS production.

5. Stress and Immune Signaling: How Are They Linked in ALD?

Cellular stress responses during alcohol exposure include oxidative stress due to metabolism of alcohol in the liver, ER stress, mitochondrial imbalance, heat shock protein induction, and inflammatory processes. Numerous mouse models have been used to study the discrete role of each of the stress responses in alcohol-mediated liver pathology. Yet, accumulating evidence suggests that these pathways cannot be regarded separately and are tightly interrelated. Similar to other inflammatory diseases [86], alcoholic liver disease is multifactorial and it is important to take into account interactions between various cellular responses for a better understanding of the pathogenesis of ALD. Based on studies so far, a clear relationship between oxidative stress and inflammation is emerging in ALD. It is increasingly apparent that in addition to gut-derived endotoxin, alcohol-induced upregulation of oxidative stress mediators plays a major part in activation of receptors, intracellular kinases, and transcription factors in innate immune cells (Figure 1). Pathways described above that are interrelated in ALD include ROS-mediated activation of TLR4 in macrophages, mitochondrial ROS regulation of transcriptional activators such as PGC-1α and HIF-1α promoting TNFα induction, ROS and autophagy associated enhancement of proinflammatory cytokine production [86], ER stress-associated innate immune cell activation, hsp-mediated activation of proinflammatory signaling kinases, and finally direct activation of transcription factors such as NFκB and STAT3 by ROS. Alcoholic liver disease exhibits enhanced inflammatory responses and exaggerated TNFα production leading to liver injury. While TNFRI knockout mice are protected from alcohol-induced liver injury [87], alcohol-induced ROS production was unaffected in TNFRI knockout mice indicating that ROS predominantly serves as a redox signal for proinflammatory cytokine production and may not be a direct toxicant to hepatocytes [87]. These studies argue against the direct role of ROS or oxidative stress in alcoholic liver injury and in fact support the notion that oxidative stress/ROS primarily affects and is indispensable to proinflammatory activation and cytokine induction in ALD creating a vicious cycle of the two pathways (Figure 1). Thus, attempts to further clarify the importance of oxidative stress and its cross-talk with inflammatory pathways will provide an insight into pathogenesis of ALD and open avenues for novel therapeutic targets.

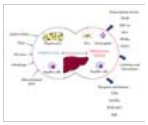

Figure 1: Oxidative stress and inflammation: interacting mechanisms in ALD. The development of alcoholic liver injury is a complex process involving oxidative stress microenvironment in the liver contributed by hepatocytes and macrophages. In addition to the activation of macrophages by gut-derived endotoxin, cellular stress responses contribute to proinflammatory cytokine production creating a tightly interrelated network in ALD.

6. Conclusion

This paper clearly implicates the role of oxidative stress in proinflammatory signaling and macrophage activation during liver injury providing a feed-forward mechanism in ALD. Therefore, targeting redox-sensitive inflammatory pathways and transcription factors offers great promise for treatment of ALD. Investigation of agents that interfere with oxidative stress mediators directly hampering inflammatory cytokine production is needed. Whether these agents will then alleviate alcoholic liver disease in patients should be tested.

BACKGROUND. Hepatocellular carcinoma (HCC) occurs in patients with hepatitis C virus-RNA positive chronic liver disease. It is important to prevent HCC with drug administration.

METHODS. A retrospective study was undertaken to evaluate the long term preventive effect of Stronger Neo-Minophagen C (SNMC) on HCC development. SNMC is a Japanese medicine that is commonly administered to patients with chronic hepatitis C to improve the serum alanine aminotransferase (ALT) level. Of 453 patients diagnosed with chronic hepatitis C retrospectively in the study hospital between January 1979 and April 1984, 84 patients (Group A) had been treated with SNMC; SNMC was given at a dose of 100 mL daily for 8 weeks, then 2–7 times a week for 2–16 years (median, 10.1 years). Another group of 109 patients (Group B) could not be treated with SNMC or interferon for a long period of time (median, 9.2 years) and were given other herbal medicine (such as vitamin K). The patients were retrospectively monitored, and the cumulative incidence of HCC and risk factors for HCC were examined.

RESULTS. The 10th-year rates of cumulative HCC incidence for Groups A and B were 7% and 12%, respectively, and the 15th-year rates were 12% and 25%. By Cox regression analysis, the relative risk of HCC incidence in patients not treated with SNMC (Group B) was 2.49 compared with that of patients treated with SNMC (Group A).

CONCLUSIONS. In this study, long term administration of SNMC in the treatment of chronic hepatitis C was effective in preventing liver carcinogenesis. ***Cancer* 1997; 79:1494–500.** © *1997 American Cancer Society.*

KEYWORDS: chronic hepatitis C, Stronger Neo-Minophagen C, glycyrrhizin, hepatocellular carcinoma.

Hepatocellular carcinoma (HCC) is one of the most common cancers in the world. Recently, greater than 80% of patients with HCC were found to have RNA for the hepatitis C virus (HCV).[1] The yearly incidence of HCC in patients with HCV-RNA positive cirrhosis ranges from 5–7% in Japan.[1–3] Kiyosawa et al.[1] reported that patients with long term abnormal serum levels after transfusion had a high probability of histological *aggravation* as well as HCC. However, there are few reports of chemopreventive studies of HCC.[5] In this study, the authors analyzed the chemopreventive action of Stronger Neo-Minophagen C (SNMC) in HCC patients. In Japan, SNMC has been used in the form of an intravenous solution, comprised of 0.2% glycyrrhizin (GL), 0.1% cysteine, and 2.0% glycine in physiologic solution. It is made by dissolving GL (200 mg), cysteine (100 mg), and glycine (2 g) in 100 mL of physiologic saline. GL is an aqueous extract of licorice root (glycyrrhizae radix), which is antiallergic and has detoxicating effects. As has been reported, the antiinflammatory mechanism of

SNMC is believed to be due to its protective effect on the hepatic cellular membrane, which may explain its ability to lower the serum transaminase level in patients with chronic hepatitis.[6,7] Glycine prevents an aldosteron-like action of GL[8] and cysteine has been found to be detoxicative as well as antiallergic through cysteine conjugation in the liver.[9] Therefore, SNMC has been developed with the expectation of the joint beneficial effect of these three components. Yamamoto et al.[10] first treated patients with chronic hepatitis with SNMC and found a distinct improvement in their ALT level. Suzuki et al.[11] confirmed its ability to suppress serum transaminase in patients with chronic hepatitis in a randomized, double blind controlled trial. Hino et al.[12] and Yasuda et al.[13] proved SNMC to be useful in the improvement of transaminase and liver histology. However, the long term effects of SNMC on patients with chronic HCV have not been confirmed. Therefore, in this study, the authors retrospectively analyzed the long term effects of SNMC on patients with chronic HCV.

MATERIALS AND METHODS

Patients

The number of patients at the study hospital diagnosed with chronic hepatitis by laparoscopy and liver biopsy between January 1979 and April 1984 was 874. Of these 453 patients had the following criteria: 1) ALT level more than twice the upper limit of the normal range (50 IU) within 6 months before liver biopsy; 2) anti-HCV (second-generation anti-HCV and enzyme-linked immunoadsorbent assays) was positive in sera preserved at −80 °C at the time of initial liver biopsy; 3) no corticosteroids, immunosuppressive agents, or antiviral agents were administered 3 months before liver biopsy; and 4) no hepatitis B surface antigens, hepatitis virus DNA, or antinuclear antibodies were detectable in the serum using radioimmunoassay and spot hybridization. In these 453 patients, 84 patients were treated with SNMC (Group A). SNMC was given at a dose of 100 mL daily for 8 weeks and 2–7 times a week for 2 to 16 years (median, 10.1 years). One hundred nine patients were not treated with SNMC (Group B) because there were no home health care professionals available to give the intravenous injection. Therefore Group B patients were given other herbal medicines (e.g., vitamin K) for 1 to 16 years (median, 9.2 years) and did not receive corticosteroids, immunosuppressive agents, or antiviral agents. The remaining 210 patients were treated with a small amount of SNMC, corticosteroids, or immunosuppressive agents. In this study, a comparison of Group A with Group B was performed with regard to hepatocarcinogenesis.

Follow-up began on the first day of SNMC treatment in Group A patients and on the day of the liver biopsy in Group B patients.

SNMC was prepared by Minophagen Pharmaceutical Company, Tokyo, Japan.

Patient Follow-Up

Clinical evaluation and biochemical and hematologic tests were performed at monthly intervals. One patient in Group A dropped out during the 7 years of follow-up. The remaining 83 patients continued to be treated with SNMC. Sixteen patients in Group B were lost to follow-up. Because the appearance of HCC was not identified in these 17 patients, they considered as censored data in the statistical analysis.[14] Deaths unrelated to HCC and patients who received treatment with antiviral agents were also classified as withdrawals and were regarded as censored. Moreover, patients treated with interferon (IFN) were regarded as withdrawals at the start of IFN treatment.

Moreover, the appearance rate of HCC was studied in 193 patients from both groups. Diagnosis of HCC was made by the typical hypervascular characteristics observed on angiography, in addition to certain features of computed tomography (CT) and ultrasonography. Microscopic examination by fine-needle biopsy was performed in patients whose angiograms did not demonstrate a typical image of HCC. Pathologic confirmation using surgically resected specimens was made in 18 patients.

Examination of HCV Genotype

HCV genotype was determined by polymerase chain reaction (PCR) with a mixed primer set derived from nucleotide sequences of the NS5 region.[15]

Liver Histology

Liver histology of chronic hepatitis was classified from the extent of fibrosis into three stages Stage I: periportal expansion; Stage II: portoportal septa; and Stage III: portocentral linkage or bridging fibrosis.[16]

Statistical Analysis

Groups A and B were compared using the Kruskal-Wallis test to assess differences in background factors; $P < 0.05$ was considered significant. ALT response to SNMC was studied by the chi-square test. HCC appearance rates were analyzed by the log rank test. A Cox proportional hazards model was used to analyze the factors contributing to the HCC appearance rate; factors examined included age, gender, histologic findings, HCV genotype, transfusion, indocyanine green retention rate at 15 (ICG R15) and SNMC admin-

TABLE 1
Profiles and Laboratory Data of the Patients at the Time of First Liver Biopsy

Parameters/Group	Group A (SNMC+; N = 84)	Group B (SNMC−; N = 109)	*P* value
Age (years)[a]	47 (31–64)	48 (30–64)	0.579
Gender (male/female)	73/11	92/17	0.833
Transfusion (+/−)	39/45	48/61	0.801
Liver histology staging (I/II or III)	51/33	61/48	0.507
HCV genotype (1b/2a or 2b)	60/16	62/21	0.486
ALT (IU)[a]	200 (100–726)	186 (104–698)	0.422
ICG R15 (%)[a]	14 (9–24)	15 (8–26)	0.767

SNMC: Stronger Neo-Minophagen C; HCV: hepatitis C virus; ALT: alanine aminotransferase; ICGR15: indocyanine green retention rate at 15 minutes.
[a] Data are expressed as the median value (range).

TABLE 2
Average ALT Levels during Follow-Up Periods between Group A and Group B

Average ALT	Normal (≦50 IU)	Abnormal (>50 IU)
Group A (SNMC (+))	30 (35.7%)	54 (64.3%)
Group B (SNMC (−))	7 (6.4%)	102 (93.6%)

ALT: alanine aminotransferase; SNMC: Stronger Neo-Minophagen C.

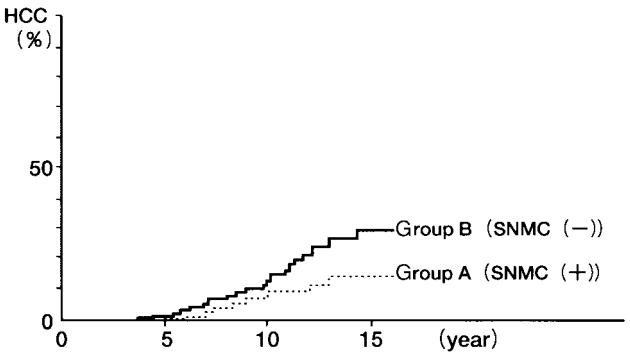

FIGURE 1. Cumulative hepatocellular carcinoma (HCC) appearance rate of Group A with Stronger Neo-Minophagen C (SNMC) administration and Group B without SNMC administration.

istration. The analysis was made using Biomedical Computer Program-p (BMDP).[17,18]

RESULTS

At the first liver biopsy, there was no significant differences between the two groups in age, gender ratio, source of infection, stage of liver histology, HCV genotype, serum ALT level, and ICG R15 (Table 1).

Serum ALT Activity during the Follow-Up Period

Table 2 shows the average ALT levels during the follow-up period. The average ALT levels declined to normal levels range, (6–50 IU) in 30 (35.7%, of the 84 patients in Group A treated with SNMC, compared with 7 (6.4%) of the 109 patients in Group B not treated with SNMC. The trend toward stabilization of ALT in Group A was statistically significant when compared with that in Group B by the chi-square test (P = 0.0000).

Cumulative HCC Appearance Rates

Figure 1 shows the cumulative HCC appearance rates in both groups. The 10-year rates in Groups A and B were 7% and 12%, respectively and the 15 year rates were 12% and 25%, respectively. The HCC appearance rate in Group A was significantly lower than that in Group B (P = 0.0319).

Figure 2 shows the cumulative HCC appearance rates based on the average ALT level for patients receiving SNMC administration. The HCC appearance rate in the 30 patients with a normal ALT level was slightly lower than that in the 54 patients with an elevated ALT level (P = 0.08).

Figure 3 shows the cumulative HCC appearance rates based on the average ALT level in Group B patients without SNMC administration. The HCC appearance rate in the 67 patients with an ALT level < 100 IU was slightly lower than that in the 42 patients with an ALT level > 100 IU (P = 0.054).

Figures 4 and 5 show the cumulative HCC appearance rates of patients based on histologic stage. In patients with histologic Stage I, there was no significant difference between patients who did or did not receive SNMC (P = 0.34). However, patients with histologic Stages II and III, the HCC appearance rate in the 33 patients treated with SNMC (Group A) was

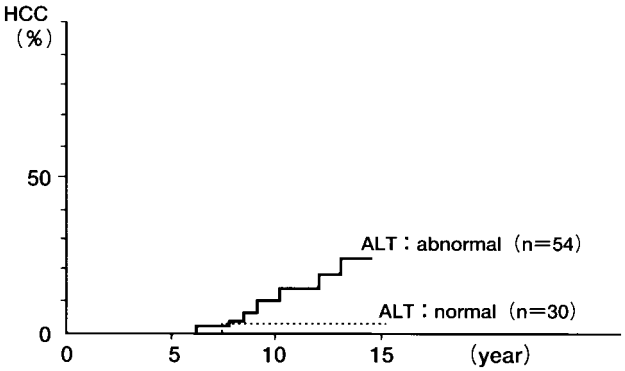

FIGURE 2. Cumulative hepatocellular carcinoma (HCC) appearance rate based on the average alanine aminotransferase level (ALT) after Stronger Neo-Minophagen C (SNMC).

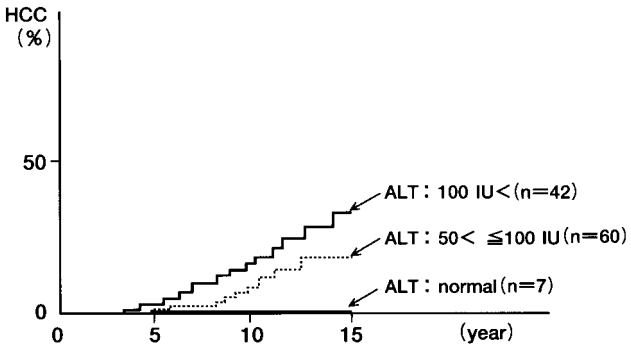

FIGURE 3. Cumulative hepatocellular carcinoma (HCC) appearance rate based on the average alanine aminotransferase (ALT) level of Group B without Stronger Neo-Minophagen C (SNMC) administration.

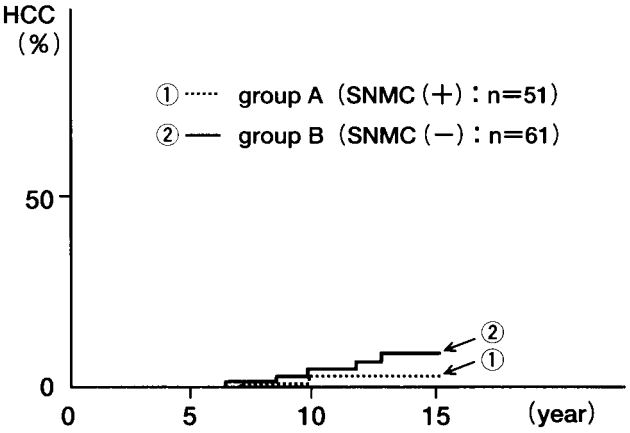

FIGURE 4. Cumulative hepatocellular carcinoma (HCC) appearance rate of patients with histologic Stage I.

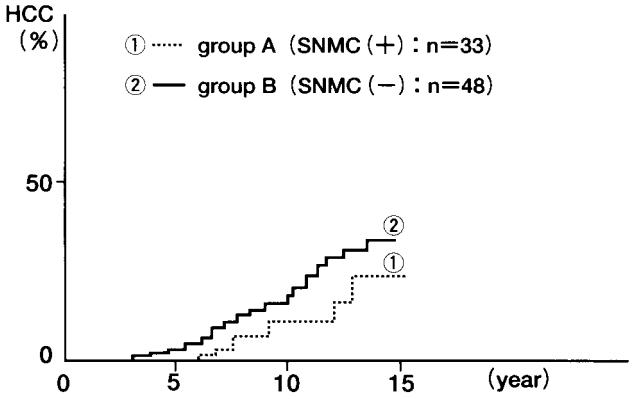

FIGURE 5. Cumulative hepatocellular carcinoma (HCC) appearance rate of patients with histologic Stages II and III.

slightly lower than that in the 48 patients who were not treated with SNMC (Group B) ($P = 0.075$).

Risk Factors for HCC

Cox regression analysis was performed with several variables, including age, gender, history of blood transfusion, histologic severity (staging), HCV genotype, ICG R15, and whether or not SNMC was administered.

Univariate analysis showed that the following four factors significantly affected the cumulative HCC appearance rate in all patients: liver histology Stage I, II, and III ($P = 0.0000$), age ($P = 0.0052$), SNMC administration ($P = 0.0319$), and average ALT level ($P = 0.0437$) (Table 3). Because the variables were mutually correlated, multivariate Cox regression analysis was performed with the four statistically significant variables in the model (Table 4). The relative risk for HCC appearance rate in patients with Stage II or III liver histology was 13.82 compared with Stage I patients, the relative risk in patients who did not receive SNMC was 2.49 compared with patients treated with SNMC.

Side Effects of SNMC Therapy

Hypokalemia (serum potassium < 3.7 mEq/mL) was observed in 9 of the 84 patients (10.7%) in Group A. No patients had a decrease <3 mEq/mL, and the values returned to the normal range (3.7–4.7 mEq/mL) after administration of 150 mg/day of spironolactone. In addition, an increase in blood pressure of $>160/90$ mm Hg was observed in 3 of the 84 patients (3.6%), but blood pressure returned to $<160/90$ mm Hg after the administration of 150–300 mg/day of spironolactone. Discontinuation of SNMC due to side effects did not occur in any of the patients.

Causes of Death

During the observation period, 8 patients in Group A (95%) died from causes including progression of HCC

TABLE 3
Factors Associated with HCC Appearance by Univariate Cox Regression Analysis

Factors	Category	Odds ratio	95% CI	*P* value
Liver histology (staging)	Stage I	1	6.30–36.60	0.0000
	Stage II, III	15.18		
Average ALT	≦50 (normal)	1	1.04~59.74	0.0437

in four patients, liver failure caused by cirrhosis in one patient, and other diseases in three patients. In Group B, 19 patients (17.4%) died from causes including progression of HCC in 13 patients, liver failure caused by cirrhosis in 1 patient, and other disease in 5 patients.

DISCUSSION

Recently many authors have confirmed the therapeutic effect of IFN in patients with chronic HCV.[19–23] However, the HCV clearance rates were more or less constantly <40–50%; the remaining cases had abnormal ALT levels after IFN therapy. In the study hospital 442 patients with positive HCV-RNA (serum samples were stored at −80 °C until analysis by a reverse transcription nested PCR) were treated with human lymphoblastoid IFN-α between January 1988 and April 1993.[24] The total dose of IFN ranged from 336 MU to 624 MU. The HCC appearance rates in histologic Stages I, II, and III were 0.1%, 0.6%, and 1.5% per year, respectively.[24] Conversely, in patients treated with SNMC the 10-year HCC appearance rates in histologic Stages I, II, and III were 3%, and 13%, respectively. Therefore, HCC appearance rates in patients treated with IFN might be slightly lower than that of patients with SNMC. However, many side effects occur during therapy with IFN and IFN is expensive. Therefore, when HCV-RNA positive patients are treated, whether or not to use IFN therapy is an issue. In patients with IFN-resistant HCV, treatments other than IFN are necessary to protect against histologic aggravation.

Finney and Somers[25] reported on the antiinflammatory effects of glycyrrhizin, and SNMC has been widely and effectively prescribed in Japan as therapy for hepatitis. However, its pharmacologic actions have not been fully clarified. Watari[7] reported that SNMC had a protective effect on the hepatic cellular membrane. Ouchi et al.[26] reported that glycyrrhizin inhibited the production of prostaglandin E_2 by activation of macrophages and the activity of phospholipase A_2 in arachinoic acid cascades in vitro.

In a randomized, double blind controlled trial, Suzuki et al.[11] reported that SNMC was a useful agent for improving serum ALT levels in patients with chronic hepatitis, 133 patients were studied, with 67 receiving 40 mL SNMC daily and 66 a placebo for 4 weeks. A significant improvement in liver function was noted in the SNMC group ($P < 0.001$). However, ALT were slightly elevated again in the second week after the medication was stopped. Hino et al.[12] reported on the effects of a large dose of SNMC (100 mL daily for 8 weeks) in 49 hospitalized patients with chronic hepatitis. All biopsy specimens obtained before and after therapy were examined blindly by the same pathologist. Histologic improvement was observed in 35 patients (71%). However, these patients were examined for only a few months. The long term effect of SNMC administration for more than several years has not been reported. In this study, the authors retrospectively investigated the long term effect of SNMC on HCC appearance rates in patients with chronic HCV. In the current study, the HCC appearance rate in 84 Group A patients who underwent long term treatment with SNMC was significantly lower than that in the 109 Group B patients who were not treated with SNMC. Nonrandomized retrospective studies may be not appropriate for the study of the efficacy of SNMC and randomized prospective studies are best suited for this purpose. However, in recent years, it is apparent that the IFN has been widely employed for patients with chronic HCV and has stabilized liver function in most patients. Conversely, SNMC can be used in general for patients with IFN-resistant HCV and in those with side effects due to the IFN therapy. Moreover, patients with chronic HCV cannot be treated with IFN or SNMC for more than 10 years. Therefore, it will be important that a randomized prospective study is begun to evaluate the long term preventive effect of SNMC on HCC development.

Based on the results of the current study, the long term administration of SNMC for chronic HCV was considered to be effective in the reduction of liver carcinogenesis. The reason why SNMC administration reduces hepatocarcinogenesis is believed to be related to the suppression of the necroinflammatory reaction in the liver and the protection against histologic aggravation. In this study, the authors examined the cumulative cirrhosis appearance rates as well. The diagnosis of cirrhosis was based on laboratory and clinical examinations, including ultrasonography, CT, and histologic examination. Seventy-one patients in Group A and 81 patients in Group B were examined by repeated liver biopsy. The 10-year rates of cumulative cirrhosis in Groups A and B were 12% and 20%, respectively, and the 15-year rates were 21% and 37%, respectively. As a result, the cirrhosis appearance rate in Group A was borderline, significantly lower than that in Group B ($P = 0.07$). Therefore, SNMC therapy could inhibit the histologic aggravation of the liver in some chronic HCV patients. Moreover, in patients treated with SNMC, HCC appearance rates in patients with normal ALT levels was lower than that of patients with abnormal ALT levels. The reduction in risk of HCC in the SNMC group may be partly due to improvement in the ALT level. Therefore, SNMC therapy, is believed to help maintain ALT levels within normal limits.

The authors conclude that normalization of ALT levels by long term administration of SNMC will assist in protecting against hepatocarcinogenesis.

Cisplatin
DNA fragmentation
Micronuclei
Nephrotoxicity
Glycyrrhizic acid
Oxidative stress

ABSTRACT

Aims: Glycyrrhizic acid (GA) is a main sweetening component of licorice roots and has been found to be associated with multiple therapeutic properties. In this study, we used GA as a protective agent against the clastogenic and nephrotoxic effects of cisplatin (CP).
Main methods: Mice were given a prophylactic treatment of GA orally at doses of 75 and 150 mg/kg body weight for seven consecutive days before the administration of a single intraperitoneal dose of CP at 7 mg/kg body weight. The modulatory effects of GA on CP-induced nephrotoxicity and genotoxicity were investigated by assaying oxidative stress biomarkers, lipid peroxidation, serum kidney toxicity markers, DNA fragmentation, alkaline unwinding, and micronuclei and by histopathological examination of the kidneys.
Key findings: A single intraperitoneal dose of cisplatin in mice enhanced renal lipid peroxidation, xanthine oxidase, and H_2O_2 generation; depleted glutathione content, activities of the anti-oxidant enzymes glutathione peroxidase, glutathione reductase, catalase, glutathione-S-transferase and quinone reductase; induced DNA strand breaks and micronucleus formation ($p<0.001$); and majorly disrupted normal kidney architecture. Pretreatment with GA prevented oxidative stress by restoring the levels of antioxidant enzymes at both doses. A significant dose-dependent decrease in DNA fragmentation, micronucleus formation ($p<0.05$), and the kidney toxicity markers BUN ($p<0.001$), creatinine ($p<0.01$), and LDH ($p<0.001$) and restoration of normal kidney histology was observed.
Significance: Our study supports the claim that the phytochemical GA has the potential to attenuate the side effects of anticancer drug overdose.

Introduction

Since ancient times, herbal products have been used to cure human diseases. These products are receiving more attention due to their low toxicity and high efficacy. Glycyrrhizin and its aglycone glycyrrhetic acid (GA) have been useful for various therapeutic purposes (Rahman and Sultana, 2007). GA is a hydrophilic part of glycyrrhizin, the active compound in licorice, which is a conjugate of two molecules of glucuronic acid and GA (Obolentseva et al., 1999). It is used as a flavoring agent in some candies, pharmaceuticals, and tobacco products and is known for its anti-inflammatory, anti-ulcer, anti-allergic, anti-oxidant, anti-viral and anti-tumor activities (Baltina, 2003). In many parts of the world, GA is used to treat patients with acute and chronic hepatitis (Rossum et al., 1999), and it has been demonstrated to induce IFN production and NK cell activity and modulate the growth response of lymphocytes by augmenting IL-2 production (Zhang et al., 1993). In addition, GA has been described as an anti-viral agent against human cytomegalovirus, herpes simplex virus type 1 and influenza virus (Pompei et al., 1979). GA has also been reported to prevent the progression of murine acquired immune deficiency syndrome (AIDS) in mice and improve the clinical symptoms in HIV-infected patients (Ito et al., 1988). Glycyrrhizin inhibits the generation of reactive oxygen species (ROS) by neutrophils at the site of inflammation and lowers lipid peroxidation in animal models of liver injury caused by ischemia reperfusion (Akamatsu et al., 1991). Glycyrrhizin inhibits abnormal cell proliferation, tumor formation and growth of many types of cancers (Nishino et al., 1984). Recently, GA was reported to reverse cisplatin resistance in hepatocellular carcinoma cells through inhibiting multidrug resistance-associated proteins (Wakamatsu et al., 2007). Glycyrrhizin has also been reported to ameliorate renal function defects in the early phase of ischemia and gentamicin-induced acute renal failure (Kang et al., 2003; Sohn et al., 2003). Zinc glycyrrhizate has a protective effect against the toxicity and anticancer activity of cisplatin in mice (Xu et al., 1993). Thus, GA can be considered as a potential protective agent against the nephrotoxicity associated with chemotherapeutics.

doi:10.1016/j.lfs.2011.06.016

Exposure to genotoxins causes carcinogenesis and teratogenicity (Kligerman et al., 1984). Damage to the structure of the affected DNA is unambiguously the main cause of mutagenesis (Khan et al., 2005). In addition to their generic growth properties, the majority of antineoplastic drugs have genotoxic effects that contribute to growth inhibition. These genotoxic effects may lead to the initiation of unrelated tumors years after the termination of chemotherapy (Manda et al., 2009). Cisplatin (CP) is a major antineoplastic drug used for the treatment of various solid tumors such as ovarian cancer, non-small-cell lung carcinoma (NSCLC) and head and neck cancer (HNC), both as a single agent and in combination with other agents (Muggia, 1991). CP is generally considered to exert its cytotoxic effect by binding to DNA, resulting in mutagenesis (Fichtinger-Schepman, 1984). The major target site of CP toxicity is the kidney: 20% of patients receiving high-dose CP develop severe renal dysfunction. Crosslinks between CP and DNA cause cytotoxic lesions in tumors and other dividing cells. DNA damaging agents are usually less toxic in nonproliferating cells, but the CP concentration in proximal tubular epithelial cells is approximately 5 times higher than the serum concentration (Kuhlmann et al., 1997). This disproportionate accumulation of CP in kidney tissue contributes to its nephrotoxicity (Arany and Safirstein, 2003).

GA has been used to treat organ toxicity caused by drug overdoses in animal models, as mentioned previously. Xu et al. have reported the protective character of GA against CP-induced organ toxicity, including nephrotoxicity. The present study is the first to examine the efficacy of GA to alleviate both genotoxicity and nephrotoxicity induced by CP by studying the status of antioxidant enzymes and markers of genotoxicity, including the alkaline unwinding assay, the DNA fragmentation assay and micronucleus induction in Swiss albino mice.

Materials and methods

Chemicals

Glycyrrhizin, EDTA, Tris, reduced glutathione (GSH), oxidized glutathione (GSSG), reduced nicotinamide adenine dinucleotide phosphate (NADPH), bovine serum albumin (BSA), bisbenzamide, proteinase K, EDTA, SDS, phenol, chloroform, isoamyl alcohol and RNase were obtained from Sigma, St. Louis, USA. Cisplatin under the brand name "Cytoplatin-50" was purchased from Cipla Ltd., India. All other reagents and solvents were of high analytical grade.

Animals

Eight-week-old adult male Swiss albino mice (20–25 g) were obtained from The Central Animal House Facility of Hamdard University, New Delhi, and were housed in a ventilated room at 25 ± 5 °C under a 12 h light/dark cycle. The animals were acclimatized for one week before the study and had access to standard laboratory feed (Hindustan Lever Ltd., Bombay, India) and water *ad libitum*. The study was approved by the Committee for the Purpose of Control and Supervision of Experimental Animals (CPCSEA) under the registration number and date 509/CPCSEA, May 28th, 2009. CPCSEA guidelines were followed for animal handling and treatment.

Experimental design

For the study of biochemical parameters and the micronucleus assay, 25 male Swiss albino mice were divided into five groups. Group I served as a saline-treated control. Group II served as a treatment control and was given single intraperitoneal injection of cisplatin (7 mg/kg b wt) freshly dissolved in saline (0.85% NaCl). GA was orally administered at two doses, 75 (dose I) and 150 (dose II) mg/kg b wt, to groups III and IV, respectively, for seven consecutive days. On the seventh day of pretreatment, a single intraperitoneal dose of CP (7 mg/kg b wt) was given to the animals in groups II, III, and IV. Group V only received dose II of GA for seven consecutive days. All the animals were sacrificed after 24 h of CP treatment. Kidneys and femur bones were removed and processed for enzyme estimation and micronucleus assays. The above-mentioned doses of compound were selected based on preliminary studies.

Micronucleus assay

For this test, mice were sacrificed 24 h after treatment with a single intraperitoneal dose of CP (7 mg/kg b wt). Bone marrow from femur bones was collected for the micronucleus assay. The time of peak response of micronucleus induction was selected as the sacrifice time based on the preliminary assays that were done to select an appropriate dose of CP that did not suppress cell proliferation in combination with the highest GA dose. The mouse bone marrow micronucleus test was carried out according to the method of Schmid (Schmid, 1975). Air-dried slides were stained with May–Grunwald and Giemsa as described by Schmid, made permanent, and coded. A total of 1500–2000 polychromatic erythrocytes (PCEs) and normochromatic erythrocytes (NCEs) were scored per animal by the same observer to determine the frequencies of micronucleated polychromatic erythrocytes (MnPCEs). To detect possible cytotoxic effects, the PCE:NCE ratio in 200 erythrocytes per animal was calculated according to Gollapudi and McFadden (Gollapudi, 1995). Coded slides were scored with a light microscope at a 1000× magnification.

DNA isolation

DNA extraction was done by the standard chloroform-isoamyl alcohol method. DNA was extracted from approximately 500 mg kidney tissue by homogenizing the tissue in 5 ml TNE buffer (50 mM Trisma, 100 mM EDTA, 0.5% SDS, pH 8.0) in a 2-ml ground glass homogenizer. Each sample was homogenized with 10 standardized pestle strokes to minimize any potential effect on DNA integrity introduced by the homogenization procedure. An equal volume of buffered phenol/chloroform/isoamyl alcohol (PCI; 25:24:1, v/v/v, pH 8.0) was then added to the sample. The sample was gently mixed, allowed to settle for 5 min and centrifuged for 5 min at 13,000 rpm at 4 °C. The aqueous layer was transferred to a new microcentrifuge tube, and the PCI extraction was repeated. The aqueous layer was then digested by 5 ml RNase (10 mg/ml) for 30 min at 37 °C, and the digest was extracted once by PCI and once by 500 ml chloroform. DNA was precipitated from the resulting aqueous layer by adding 2 volumes of absolute ethanol and 1/10 volume of 3 M sodium acetate, pH 5.2. The sample was then centrifuged (13,000 rpm, 15 min), and the resulting pellet was rinsed with 500 ml of 70% ethanol and air-dried. The amount of DNA was quantified spectrophotometrically at 260 and 280 nm. A 2 mg/ml DNA sample was dissolved in 1 ml TE buffer (10 mM Trisma, 1 mM EDTA) and subsequently used in the DNA alkaline unwinding assay.

Alkaline unwinding assay

In the alkaline unwinding assay, the rate of the transition of double stranded DNA (dsDNA) to single stranded DNA (ssDNA) under predefined alkaline denaturing conditions was proportional to the number of breaks in the phosphodiester backbone and thus was used as a measure of DNA integrity. Bisbenzamide was used as a fluorescent DNA-binding dye to allow the quantification of various types of DNA. To determine the fluorescence of dsDNA, ssDNA and partially unwound DNA (auDNA), three equal portions of each diluted DNA sample were prepared. The amount of dsDNA was obtained from the fluorescence of a sample without any treatment, while the amount of ssDNA was determined from a sample that had been boiled for

30 min. The fluorescence of a DNA sample subjected to alkaline treatment (pH 12.2) on ice for 30 min provided an estimate of the amount of auDNA. The fluorescence of initial or dsDNA was determined by placing 100 mmol DNA, 100 ml NaCl (25 mM) and 2 ml SDS (0.5%) in a prechilled test tube, followed by the addition of 3 ml 0.2 M potassium phosphate, pH 9, and 3 ml bisbenzamide (1 mg/ml). The contents were mixed and allowed to react in the dark for 15 min to allow the fluorescence to stabilize. The fluorescence of the sample was measured using a spectrofluorimeter (excitation: 360 nm; emission: 450 nm). The fluorescence of ssDNA was determined as above, but using the DNA sample that had been boiled for 30 min to completely unwind the DNA. Fifty microliters of NaOH (0.05 N) was rapidly mixed with 100 ml DNA in a pre-chilled test tube (Shugart, 1988). The mixture was incubated on ice in the dark for 30 min, followed by rapid addition and mixing of 50 ml HCl (0.05 N). This was followed immediately by the addition of 2 ml SDS (0.5%), and the mixture was forcefully passed through a 21-gauge needle six times. The fluorescence of auDNA was measured as described above in triplicate, and the average was reported. The ratio between dsDNA to total DNA (F value) was determined as follows:

$$\text{F value} = (\text{auDNA} - \text{ssDNA}) / (\text{dsDNA} - \text{ssDNA}),$$

where auDNA, ssDNA and dsDNA were the degrees of fluorescence from the partially unwound, single stranded and double stranded samples, respectively. The F-value was inversely proportional to the number of strand breaks present and thus could be used as an indicator of DNA integrity.

Gel electrophoresis and DNA fragmentation

DNA samples were mixed with 10 ml loading solution (10 mM EDTA (pH 8.0), 1% (w/v) bromophenol blue and 40% (w/v) sucrose) preheated to 70 °C. Samples were loaded onto a 1.8% (w/v) agarose gel and sealed with 0.8% (w/v) low melting point agarose. DNA fragments were separated by electrophoresis at 25 V for 12 h at 4 °C in TBE buffer. DNA was visualized using ethidium bromide and photographed by a digital camera.

Post-mitochondrial supernatant preparation

Kidneys were removed quickly, cleaned of extraneous material and immediately perfused with ice-cold saline (0.85% NaCl). The kidneys were homogenized in chilled phosphate buffer (0.1 M, pH 7.4) containing KCl (1.17%) using a Potter–Elvehjen homogenizer. The homogenate was filtered through muslin cloth and centrifuged at 800×*g* for 5 min at 4 °C by a REMI cooling centrifuge to separate the nuclear debris. The aliquot obtained was centrifuged at 12,000 rpm for 20 min at 4 °C to obtain PMS, which was used as a source of enzymes. All biochemical estimations were completed within 24 h of animal sacrifice (Khan and Sultana, 2005).

Reduced glutathione estimation

One-milliliter samples of PMS were precipitated with 1.0 ml sulfosalicylic acid (4%), kept at 4 °C for 1 h and then centrifuged at 1200×*g* for 20 min at 4 °C. The assay mixture contained 0.1 ml filtered aliquot, 2.7 ml phosphate buffer (0.1 M, pH 7.4) and 0.2 ml 1, 2-dithiobisnitrobenzoic acid (DTNB; 100 mM) in a total volume of 3.0 ml. The yellow color that developed was quantified at 412 nm on a spectrophotometer (Jollow et al., 1974).

Glutathione reductase activity

GR activity was determined by the method of Carlberg and Mannervik. The reaction mixture consisted of 1.65 ml phosphate buffer (0.1 M, pH 7.6), 0.1 ml EDTA (0.5 mM), 0.05 ml GSH (1 mM), 0.1 ml NADPH (0.1 mM) and 0.1 ml 10% PMS in a total volume of 2 ml. Enzyme activity was quantified at 25 °C by measuring the disappearance of NADPH at 340 nm and was calculated as nmol NADPH oxidized per min per mg protein using a molar extinction coefficient of $6.22\times10^3\ M^{-1}\ cm^{-1}$ (Carlberg and Mannervik, 1975).

Glutathione peroxidase activity

The reaction mixture consisted of 1.49 ml phosphate buffer (0.1 M, pH 7.4), 0.1 ml EDTA (1 mM), 0.1 ml sodium azide (1 mM), 0.05 ml glutathione reductase (1 IU/ml), 0.05 ml GSH (1 mM), 0.1 ml NADPH (0.2 mM), 0.01 ml H_2O_2 (0.25 mM) and 0.1 ml 10% PMS in a total volume of 2 ml. The disappearance of NADPH at 340 nm was recorded at 25 °C. Enzyme activity was calculated as nmol NADPH oxidized per min per mg protein using a molar extinction coefficient of $6.22\times10^3\ M^{-1}\ cm^{-1}$ (Mohandas et al., 1984).

Glutathione S-transferase activity

The reaction mixture consisted of 2.5 ml phosphate buffer (0.1 M, pH 6.5), 0.2 ml GSH (1 mM), 0.2 ml CDNB (1 mM), and 0.1 ml of the cytosolic fraction (10%) in a total volume of 3.0 ml. Changes in absorbance were recorded at 340 nm, and enzymatic activity was calculated as nmol CDNB conjugate formed per min per mg protein using a molar extinction coefficient of $9.6\times10^3\ M^{-1}\ cm^{-1}$ (Habig et al., 1974).

Malondialdehyde formation

The reaction mixture contained 0.60 ml phosphate buffer (0.1 M, pH 7.4), 0.2 ml microsomes and 0.2 ml ascorbic acid (100 mM) in a total volume of 1.0 ml. The reaction mixture was incubated at 37 °C in a shaking water bath for 1 h and stopped by adding 1.0 ml 10% trichloroacetic acid (TCA). Following the addition of 1.0 ml 0.67% thiobarbituric acid (TBA), all tubes were placed in a boiling water bath for 20 min and then shifted to a crushed ice-bath before centrifuging at 2500×*g* for 10 min. The amount of malondialdehyde (MDA) formed in each of the samples was assessed by measuring the optical density of the supernatant at 535 nm against a reagent blank using a spectrophotometer (Perkin Elmer, Lamda EZ 201). The results were expressed as nmol MDA formed per hour per gram tissue at 37 °C using a molar extinction coefficient of $1.56\times10^5\ M^{-1}\ cm^{-1}$ (Wright et al., 1981).

Xanthine oxidase activity

The reaction mixture consisted of 0.2 ml PMS incubated for 5 min at 37 °C with 0.8 ml phosphate buffer (0.1 M, pH 7.4). The reaction was started by adding 0.1 ml xanthine (9 mM) and was kept at 37 °C for 20 min. The reaction was terminated by adding 0.5 ml ice-cold perchloric acid (PCA; 10% v/v). After 10 min, 2.4 ml distilled water was added, and the samples were centrifuged at 4000 rpm for 10 min. The amount in mg of uric acid formed per minute per mg protein was recorded at 290 nm (Stirpe and Della Corte, 1969).

Catalase activity

The reaction mixture consisted of 1.95 ml phosphate buffer (0.1 M, pH 7.4), 1.0 ml hydrogen peroxide (0.019 M) and 0.05 ml 10% PMS in a final volume of 3 ml. Changes in absorbance were recorded at 240 nm. Catalase activity was calculated as nmol H_2O_2 consumed per min per mg protein (Claiborne, 1985).

Quinone reductase activity

The reaction mixture consisted of 2.13 ml Tris–HCl buffer (25 mM, pH 7.4), 0.7 ml BSA, 0.1 ml FAD, 0.02 ml NADPH (0.1 mM), and 50 μL (10%) PMS in a final volume of 3 ml. The reduction of dichlorophenolindophenol (DCPIP) was recorded calorimetrically at 600 nm, and enzyme activity was calculated as nmol of DCPIP reduced per min per mg protein using a molar extinction coefficient of $2.1 \times 10^4\ M^{-1}\ cm^{-1}$ (Benson et al., 1980).

Estimation of blood urea nitrogen

Protein-free filtrate was prepared by adding serum and an equal amount of 10% TCA. Then the mixture was centrifuged at 2000 rpm, and supernatant was taken. To 0.5 ml protein-free filtrate, 3.5 ml of distilled water, 0.8 ml diacetylmonoxime (2%) and 3.2 ml sulfuric acid–phosphoric acid reagent (prepared by mixing 150 ml 85% phosphoric acid with 140 ml water and 50 ml concentrated sulfuric acid) were added. The reaction mixture was placed in a boiling water bath for 30 min and then cooled to room temperature. The absorbance was read at 480 nm (Kanter, 1975).

Quantification of creatinine

Protein-free filtrate was prepared. To 1.0 ml serum, 1.0 ml sodium tungstate (5%), 1.0 ml sulfuric acid (0.6 N) and 1.0 ml distilled water were added. After mixing thoroughly, the sample was centrifuged at 800 ×*g* for 5 min. The supernatant was added to a mixture containing 1.0 ml picric acid (1.05%) and 1.0 ml sodium hydroxide (0.75 N). The absorbance at 520 nm was read after exactly 20 min (Hare, 1950).

Assay for hydrogen peroxide

Microsomes (2.0 ml) were suspended in a 1.0-ml solution containing phenol red (0.28 nM), horseradish peroxidase (8.5 units), dextrose (5.5 nM) and phosphate buffer (0.05 M, pH 7.0) and were incubated at 37°C for 60 min. The reaction was stopped by the addition of 0.01 ml NaOH (10 N) and then centrifuged at 800 ×*g* for 5 min. The absorbance of the supernatant was recorded at 610 nm against a reagent blank. The quantity of H_2O_2 produced was expressed as nmol H_2O_2 per hour per gram tissue based on the standard curve of H_2O_2 oxidized phenol red (Pick and Keisari, 1981).

Lactate dehydrogenase activity

The assay mixture consisted of serum, NADH (0.02 M), sodium pyruvate (0.01 M), phosphate buffer (0.1 M, pH 7.4) and distilled water in a total volume of 3 ml. Enzyme activity was recorded at 340 nm, and activity was calculated as nmol NADH oxidized per min per mg protein (Kornberg, 1955).

Estimation of protein concentration

The protein concentration in all samples was determined by the method of Lowry et al.(1951).

Histopathological examination

The kidneys were quickly removed after sacrifice of mice and preserved in 10% neutral buffered formalin for histopathological processing. The kidneys were embedded in paraffin wax and longitudinally sectioned with a microtome. Hematoxylin and eosin staining of the sections was observed under an Olympus microscope.

Statistical analysis

Differences between groups were analyzed using analysis of variance (ANOVA), followed by Dunnet's multiple comparisons test. All data points are presented as the treatment group mean ± standard error of the mean (S.E.).

Results

Effects of GA pretreatment on renal glutathione, its dependent enzymes and the antioxidant enzyme system

Table 1 shows that CP administration leads to a 60% reduction in renal GSH. In addition, there was a marked inhibition of GR by 69%, GST by 60% and GPx by 52% compared to the control (Table 1). Pretreatment with GA restored renal GSH content by 64% at dose I and 83% at dose II, GR by 66% at dose I and 200% at dose II, GST by 89% at dose I and 103% at dose II and GPx by 45% at dose I and 92% at dose II. Similarly, CP treatment inhibited catalase by 53%, as shown in Table 2, which was restored by prophylactic GA treatment by 56% at dose I and 90% at dose II.

Table 2 shows that CP administration enhances XO levels by 183%, MDA formation by 72% and H_2O_2 by 137% in comparison to the control. In addition, there was marked inhibition of QR by 55% following CP administration as compared to the control (Table 2). Pretreatment with GA restored renal XO by 41% at dose I and 53% at dose II, MDA formation by 18% at dose I and 29% at dose II and H_2O_2 by 35% at dose I and 43% at dose II (Table 2). Quinone reductase (QR) was restored by 91% at dose I and 114% at dose II (Table 2).

Effects of GA pretreatment on renal toxicity marker enzymes

The effects of the prophylactic administration of GA on cisplatin-mediated leakage of kidney toxicity marker enzymes and on the cytotoxicity marker enzyme LDH in serum are shown in Table 3. Only the CP-treated group induced BUN by 80%, creatinine by 84% and LDH by 133% compared with the control. Marked inhibition of BUN (30% at dose I and 38% at dose II) and creatinine levels (10% at dose I and 32%

Table 1
Results of pre-treatment of GA on antioxidant enzymes like GSH, GST, GR and GPX on Cisplatin administration in kidney of Swiss Albino mice.

Treatment regimen per group	GSH (n mol CDNB Conjugate formed/g tissue)	GST (n mol CDNB conjugate formed/min/mg protein)	GR (n mol NADPH Oxidized/min/ mg protein)	GPX (n mol NADPH Oxidized/min/ mg protein)
Group I (control)	0.92 ± 0.001	115.9 ± 1.853	282.7 ± 1.044	281.1 ± 2.041
Group II (only CP)	0.42 ± 0.001***	46.88 ± 2.124***	87.8 ± 0.453***	133.6 ± 0.523***
Group III (CP + GA D1)	0.69 ± 0.0004$^{\#\#\#}$	88.50 ± 3.759$^{\#\#}$	145.8 ± 0.802^{NS}	193.9 ± 12.105$^{\#\#}$
Group IV (CP + GA D2)	0.77 ± 0.001$^{\#\#\#}$	95.03 ± 3.243$^{\#\#\#}$	263.5 ± 7.137$^{\#\#\#}$	256.7 ± 0.704$^{\#\#\#}$
Group V (only GA D2)	0.86 ± 0.003	102.7 ± 5.961	280.4 ± 2.632	265.2 ± 5.063

Results represent mean ± SE of five animals per group. Cisplatin administration resulted in significant decrease in the level of GSH, GST, GR and GPx. Prophylactic treatment with GA at both doses significantly modulated the alterations induced by CP in mice kidney. Results obtained are significantly different from Control group ($^{***}p<0.001$). Results obtained are significantly different from CP treated group ($^{\#\#}p<0.01$) and ($^{\#\#\#}p<0.001$). Whereas, Results obtained are not significantly different from CP treated group (NS). Cisplatin—CP, Glycyrrhizic acid—GA; D1 = 75 mg/kg b wt; D2 = 150 mg/kg b wt.

Table 2
Results of pre-treatment of GA on antioxidant enzymes like G6PD, XO, LPO, QR and catalase on Cisplatin administration in kidney of Swiss Albino mice.

Treatment regimen per group	H_2O_2 (n moles H_2O_2/g tissue)	XO (μg uric acid formed/min/mg protein)	LPO (n mol MDA formed/hr/g tissue)	QR (nmol NADPH oxidized/min/mg protein)	Catalase (nmol H_2O_2 consumed/min/mg protein)
Group I (control)	59.8 ± 6.586	3.64 ± 0.338	5.16 ± 0.259	164.1 ± 7.823	130.3 ± 0.224
Group II (only CP)	141.6 ± 3.293***	10.30 ± 0.720***	8.89 ± 0.520***	73.7 ± 4.249***	61.57 ± 0.32***
Group III (CP + GA D1)	91.6 ± 2.813##	6.03 ± 0.024##	7.25 ± 0.105##	140.6 ± 8.452###	95.85 ± 0.029#
Group IV (CP + GA D2)	80.1 ± 6.257###	4.80 ± 0.059###	6.35 ± 0.369###	158.0 ± 4.679###	116.9 ± 0.388##
Group V (only GA D2)	61.9 ± 1.742	4.66 ± 0.309	5.96 ± 0.016	160.7 ± 17.840	121.0 ± 0.330

Results represent mean ± SE of five animals per group. There was marked increase in the levels of H_2O_2, XO and LPO, which was significantly restored to normal level by the pre treatment of GA. Cisplatin administration resulted in significant decrease in the activity of QR and catalase. Prophylactic treatment with GA at both doses significantly increased the activity of these enzymes in mice kidney. Results obtained are significantly different from Control group (***$p<0.001$). Results obtained are significantly different from CP treated group (##$p<0.01$) and (###$p<0.001$). Cisplatin—CP, Glycyrrhizic acid—GA; D1 = 75 mg/kg b wt; D2 = 150 mg/kg b wt.

at dose II) was observed in the GA-treated groups. LDH was inhibited by 34% at dose I and 46% at dose II.

Effects of GA pretreatment on genotoxicity

In the DNA alkaline unwinding assay (Fig. 1C), a 53% decrease in the F-value was noted compared to the control group, whereas the F-value increased by 71% at dose I and 101% at dose II of GA. Similarly, Fig. 1A shows that there was a 140% higher induction of micronuclei, and this level decreased with prophylactic treatment of GA by 36% at dose I and 24% at dose II. The estimated PCE:NCE ratio in bone marrow preparations shows a statistical decrease in hematopoiesis by 34% as a result of CP treatment compared to the control (Fig. 1B). GA pretreatment at dose I increased the PCE:NCE ratio by 28%; dose II increased the ratio by 46%, indicating a reversal of the cytotoxic effects caused by CP administration to mice. DNA damage was estimated by smearing and lack of an intact control band; only the GA-treated groups had less smearing and an intact band (Fig. 1D). Fig. 1D also shows that there was significant DNA fragmentation in the treated group compared to the control group, while there was less fragmentation in the GA-pretreated groups. GA treatment restored DNA integrity.

Histopathological examination

Normal glomerular and tubular histology was seen both in cortical and medullar regions of kidneys in control rats (Fig. 2A). However, CP caused extremely severe glomerular and peritubular congestion in group II, as shown in Fig. 2B. There was also severe invasion of inflammatory cells into the interstitium and the perivascular and subvascular areas in both cortical and medullar sections from the CP-treated group. In addition to these features of CP nephrotoxicity, necrosis of tubular structures was seen in proximal and distal regions. The inner cortical and outer medullar regions exhibited more extreme architectural damage than the inner medullar regions of the kidney. The nephrosis was characterized by widespread degeneration of tubular architecture, tubular congestion, swelling and necrosis. In contrast, renal sections obtained from animals that were pretreated with GA at dose I had a partial reduction of the histological features of renal injury (Fig. 2C). GA pretreatment at dose II was associated with more significant reductions in injury, similar to control rat kidneys (Fig. 2D). A higher dose of GA alone did not cause any adverse effects in the overall normal architecture of kidneys, as shown in Fig. 2E.

Table 3
Results of pre-treatment of GA on serum kidney toxicity markers BUN, Creatinine and LDH on Cisplatin administration in kidney of Swiss Albino mice.

Treatment regimen per group	BUN (mg/dl) IU/L	Creatinine (mg/dl) IU/L	LDH (n mol NADH oxidized/min/mg protein)
Group (I control)	17.27 ± 2.071	1.94 ± 0.023	349.1 ± 10.44
Group II (only CP)	31.07 ± 1.229***	3.57 ± 0.142***	814.6 ± 11.71***
Group III (CP + GA D1)	21.72 ± 0.142###	3.22 ± 0.128NS	539.5 ± 2.89###
Group IV (CP + GA D2)	19.27 ± 0.444###	2.44 ± 0.057##	439.0 ± 15.95###
Group V (only GA D2)	17.68 ± 2.069	2.26 ± 0.059	404.6 ± 10.44

Results represent mean ± SE of five animals per group. Results obtained are significantly different from Control group (***$p<0.001$). As evident from the table there was substantial increase in the serum levels of BUN, Creatinine and LDH. The levels of these toxicity markers was abrogated by the prophylactic treatment of GA. Results obtained are significantly different from CP treated group (##$p<0.01$) and (###$p<0.001$). Results obtained are not significantly different from CP treated group (NS). Cisplatin—CP, Glycyrrhizic acid—GA; D1 = 75 mg/kg b wt; D2 = 150 mg/kg b wt.

Discussion

Cisplatin is a potent chemotherapeutic agent that has gained widespread use against various malignant tumors in different experimental animals (Kociba et al., 1970). Its use, however, is limited by its nephrotoxicity and genotoxicity. The highest concentration of CP is found in cytosol, mitochondria, nuclei, and microsomes. Genomic instability is often considered to be the hallmark of cancer, and it has been shown previously that CP treatment leads to genotoxicity and DNA strand breaks, as measured by the alkaline unwinding assay. These breaks are believed to result from the interaction of CP with DNA through the binding with N^7 of purine bases, forming CP–DNA adducts (Wozniak et al., 2004). The high mutagenic potency of CP raises the concern that its use in cancer chemotherapy may be responsible for secondary malignancies, which have been observed in animals and some cured patients treated with CP (Kempf and Ivankovic, 1986; Greene, 1992; Pillaire et al., 1994).

In the present study, the development of these mutagenic parameters was seen after CP treatment *in vivo*, supporting earlier observations of its genotoxic properties (Pillaire et al., 1994; Overbeck et al., 1996). There was a concurrent decline in the F-value in the DNA alkaline unwinding assay and differences observed with agarose gel electrophoresis, which are markers for DNA integrity (Fig. 1D). Our results show that there was significant DNA fragmentation in the CP-treated group compared to the control group, whereas there was less fragmentation in the GA-pretreated group. During DNA fragmentation, DNA damage is estimated by smearing and lack of an intact band on an agarose gel. An intact band was observed in the group pretreated with GA at dose II and in the control group only.

Injury due to oxidative stress is actively involved in the pathogenesis of CP-induced acute kidney injury. Many authors have found that genotoxicity and chromosomal instability induced by many agents are strongly correlated with the parameters of oxidative stress. Reactive oxygen species (ROS) directly act on cell components, including lipids, proteins, and DNA, and destroy their structure. ROS are produced in cells via the xanthine–xanthine oxidase system, mitochondria, and NADPH oxidase. In the presence of CP, ROS are produced by all these pathways and are implicated in the pathogenesis of acute CP-induced renal injury

(Kawai et al., 2006). CP has been shown to inhibit the activity of antioxidant enzymes (glutathione-S-transferase, catalase, and glutathione reductase) in rat kidneys (Afifi, 2010). Consistent with previous studies, CP administration leads to a depletion in renal glutathione content and inhibits the activities of the renal anti-oxidant enzymes glutathione peroxidase, glutathione reductase, catalase and glutathione S-transferase. Glutathione and dependent enzymes, namely, GR, GPx and GST, were significantly restored to normal levels in GA-pretreated groups. Simultaneously, GA pretreatment restored the depleted levels of H_2O_2, QR and catalase. Earlier reports suggested that CP induces nephrotoxicity by initiating lipid peroxidation and depleting cellular thiols (Jin-Gang and Lindup, 1993). In the present study, we have observed a noticeable increase of LPO activity in the CP-treated group; further, it was found that LPO is significantly attenuated by GA pretreatment.

Chemoprotective agents are capable of exerting their antigenotoxic effects by one or a combination of mechanisms, such as inhibiting the formation of reactive carcinogenic metabolites, inducing enzymes that detoxify carcinogens, scavenging reactive oxygen species, influencing apoptosis and inhibiting cell proliferation. GA is known to possess anti-inflammatory, anticarcinogenic, nephroprotective, and immunomodulatory effects and was proposed to be a possible chemopreventive drug (Akamatsu et al., 1991; Wakamatsu et al., 2007; Xu et al., 1993; Kelloff et al., 1994). In the present work, it was found that GA pretreatment of CP-treated mice significantly decreased MDA formation and XO levels. Concomitant modulation of antioxidant status was also observed. Serum kidney toxicity markers were significantly altered, as observed in earlier studies (Ibrahim et al., 2010). Pretreatment with GA appreciably depleted serum toxicity markers, thus revealing a role for GA in modulating kidney toxicity. Mice treated with GA had significantly lower BUN, creatinine and LDH levels than those receiving only CP; thus, GA ameliorates nephrotoxicity. It is evident from this study that GA was not only able to reduce cellular damage but also suppressed DNA fragmentation and the formation of MnPCEs *in vivo*, which are the hallmarks of CP-induced genotoxicity (Mora et al., 2002). The decrease in the PCE:NCE ratio, a mark of cytotoxicity in the bone marrow of mice

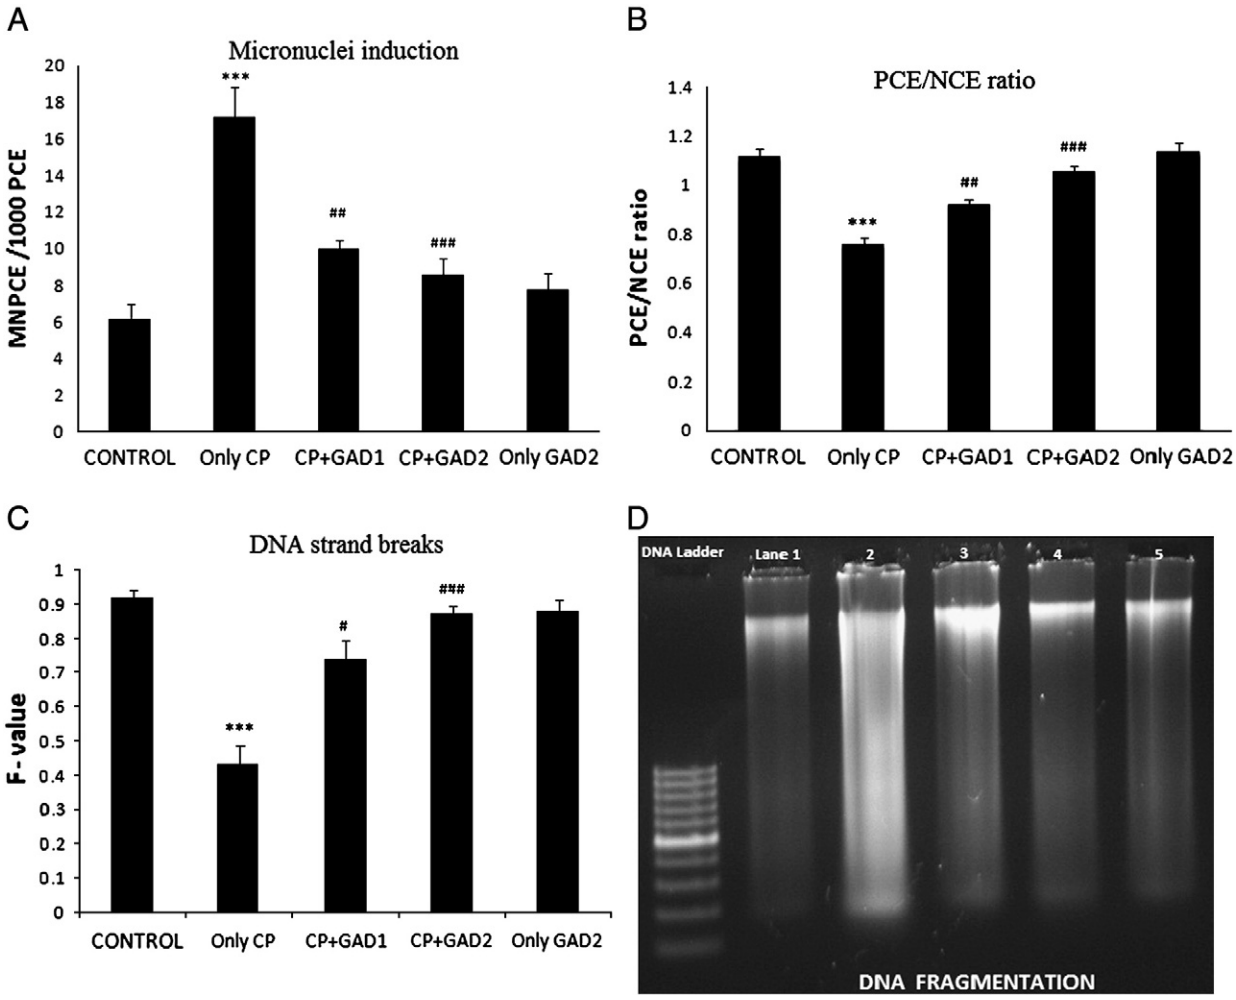

Fig. 1. Effect of GA on CP-altered markers of genotoxicity. 1 (A) Micronucleus induction in the bone marrow of mice: there was a marked increase ($p<0.001$) in the micronucleus content of the polychromatic erythrocytes (PCE) in the bone marrow of mice due to CP treatment compared to untreated controls. However, pretreatment with GA suppressed micronucleus formation significantly at dose I ($p<0.01$) and dose II ($p<0.001$). 1 (B) PCE:NCE ratios in the bone marrow of mice: There was a significant decrease in the PCE:NCE ratio in the CP-treated group, displaying induction of cytotoxicity in the bone marrow cells of Swiss albino mice. Prophylactic treatment with GA at both doses significantly reversed the cytotoxic effects of CP. Dose I of GA did not cause any toxicity. 1 (C) DNA strand breaks: results from the alkaline unwinding assay revealed a significant increase in DNA strand breaks resulting from CP injection in mice. GA treatment protected DNA from CP-induced breaks significantly at D1 ($p<0.05$) and D2 ($p<0.001$). 1 (D) Agarose (1.5%) gel electrophoresis of DNA obtained from mouse kidney: lane 1—control; lane 2—CP alone; lane 3—CP + GA D1; lane 4—CP + GA D2; lane 5—GA D2 alone; lane 6—mid-range DNA ladder. From the gel images, it is evident that CP treatment introduced DNA fragmentation, marked by the smearing of DNA in lane 2 compared to the untreated control in lane 1. There is a decrease in DNA smearing as a result of GA pretreatment at both doses in the mouse kidney. The results represent the mean ± SE of five animals per group. The results obtained are significantly different from those of the control group ($^{***}p<0.001$) and those of the CP-treated group ($^{\#}p<0.05$; $^{\#\#}p<0.01$; $^{\#\#\#}p<0.001$). CP = Cisplatin; GA = Glycyrrhizic acid; D1 = 75 mg/kg b wt; D2 = 150 mg/kg b wt.

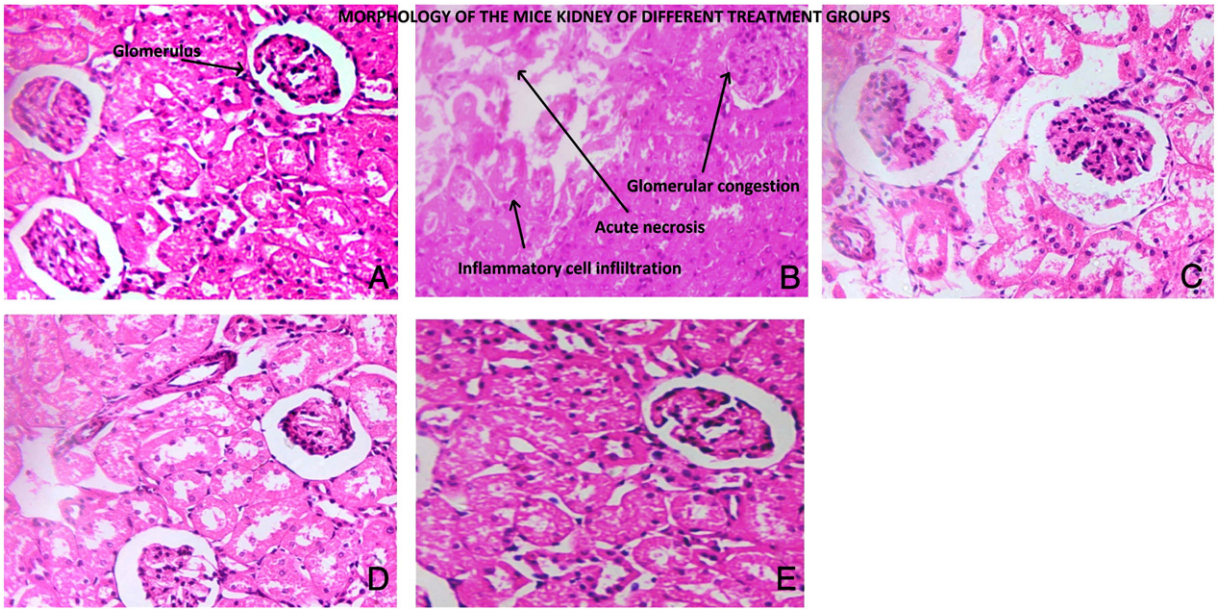

Fig. 2. Mouse kidney histology (400× magnification): Representative histological abnormalities in the regions including the inner cortical and outer medullar areas of the kidney, which are the main target sites of cisplatin nephrotoxicity, following a single intraperitoneal injection of CP and the effects of GA prophylactic treatment. (A) Normal kidney histology from a control rat. (B) After CP administration, many cortical convoluted tubules were invaded by necrotic epithelial cells or vacuolated swell cells, glomeruli were swollen, and the Bowman's capsular space was reduced. Shown are numerous inflammatory cells in the glomerular and tubular structures in the outer medulla. (C) Administration of dose I of GA (75 mg/kg b wt) partially prevented the cytotoxic damage induced by CP, as indicated by the slight cellular vacuolization of cortical convoluted tubules and few inflammatory cells. (D) Dose II of GA (150 mg/kg b wt) almost fully protected the kidney tissue from destruction induced by CP, as evident from the normal histology of the inner cortical region. (E) Dose II of GA alone did not produce abnormalities in kidney histology.

due to CP treatment, as observed in previous studies (Attia et al., 2008), was also suppressed in the GA-pretreated groups.

Our results suggest that one of the major therapeutic effects of GA in CP-induced nephrotoxicity and genotoxicity might result from its ability to directly scavenge free radicals and potentiate the antioxidant defense system. Earlier studies in rats have demonstrated that CP induces acute tubular necrosis of the straight portion of the proximal tubule, located at the cortico-medullary junction (Vickers et al., 2004). In accordance with earlier studies, CP-treated mice were found to have glomerular and peritubular congestion, with inflammatory cells invading the cortical and medullar regions of the kidneys. The main histological finding of this study was that pretreatment with GA influenced the recovery of abnormal kidney architecture induced by CP. The findings of our study are consistent with those of a previous study that revealed a protective nature of GA against CP-induced acute nephrotoxicity (Xu et al., 1993).

In conclusion, a plausible mechanism of the protective action of GA might be at least partly due to its free radical scavenging activity. Overall, these studies suggest the protective potential of GA against CP-induced genotoxicity and nephropathy; however, future studies need to be conducted at the molecular level to determine if GA can effectively inhibit the ability of CP to induce genetic damage in normal cells without interfering with its capacity to reduce tumor growth in cells treated with CP. Experiments at the molecular level will reveal the actual mechanism of action of GA, and its use may thus increase the therapeutic window of CP in cancer patients.

Conflict of interest statement

The authors of the present research work do not have any conflict of interest to present this research work.

REVIEW ARTICLE

Review of Pharmacological Effects of *Glycyrrhiza* sp. and its Bioactive Compounds

Marjan Nassiri Asl and Hossein Hosseinzadeh*
Department of Pharmacology, Faculty of Medicine, Qazvin University of Medical Sciences, Qazvin, IR Iran

The roots and rhizomes of licorice (*Glycyrrhiza*) species have long been used worldwide as a herbal medicine and natural sweetener. Licorice root is a traditional medicine used mainly for the treatment of peptic ulcer, hepatitis C, and pulmonary and skin diseases, although clinical and experimental studies suggest that it has several other useful pharmacological properties such as antiinflammatory, antiviral, antimicrobial, antioxidative, anticancer activities, immunomodulatory, hepatoprotective and cardioprotective effects. A large number of components have been isolated from licorice, including triterpene saponins, flavonoids, isoflavonoids and chalcones, with glycyrrhizic acid normally being considered to be the main biologically active component. This review summarizes the phytochemical, pharmacological and pharmacokinetics data, together with the clinical and adverse effects of licorice and its bioactive components. Copyright © 2008 John Wiley & Sons, Ltd.

Keywords: licorice; *Glycyrrhiza glabra*; glycyrrhizin; glabridin; glycyrrhitinic acid; isoliquiritigenin.

INTRODUCTION

Licorice species are perennial herbs native to the Mediterranean region, central to southern Russia, and Asia Minor to Iran, now widely cultivated throughout Europe, the Middle East and Asia (Blumenthal *et al.*, 2000). They have been used medically since at least 500 BC and licorice has been described as 'the grandfather of herbs' (Ody, 2000). The genus *Glycyrrhiza* (Leguminosae) consists of about 30 species including *G. glabra*, *G. uralensis*, *G. inflata*, *G. aspera*, *G. korshinskyi* and *G. eurycarpa*, *G. glabra* also includes three varieties: Persian and Turkish licorices are assigned to *G. glabra* var. *violacea*, Russian licorice is *G. glabra* var *gladulifera*, and Spanish and Italian licorices are *G. glabra* var. *typica* (Nomura *et al.*, 2002). It is also known as liquorice, kanzoh, gancao, sweet root and yasti-madhu (Blumenthal *et al.*, 2000; Nomura *et al.*, 2002).

ACTIVE CONSTITUENTS

Saponins

Licorice root contains triterpenoid saponins (4–20%), mostly glycyrrhizin, a mixture of potassium and calcium salts of glycyrrhizic acid (also known as glycyrrhizic or glycyrrhizinic acid, and a glycoside of glycyrrhetinic acid) which is 50 times as sweet as sugar (Blumenthal *et al.*, 2000). Other triterpenes present are liquiritic acid, glycyrretol, glabrolide, isoglaborlide and licorice acid (Williamson, 2003). Recently, it was shown that high concentration glycyrrhizin production is possible within a very short production period under controlled environments (Afreen *et al.*, 2005).

Flavonoids

Other constituents include flavonoids and chalcones (which are responsible for the yellow color of licorice) such as liquiritin, liquiritigenin, rhamnoliquiritin, neoliquiritin, chalcones isoliquiritin, isoliquiritigenin, neoisoliquiritin, licuraside, glabrolide and licoflavonol (Williamson, 2003). Recently 5,8-dihydroxy-flavone-7-O-beta-D-glucuronide, glychionide A, and 5-hydroxy-8-methoxyl-flavone-7-O-beta-D-glucuronide, glychionide B were isolated from the roots of *G. glabra* (Li *et al.*, 2005). The retrochalcones, licochalcone A, B, C, D and echinatin, were recently isolated from the roots of *G. inflata* (Haraguchi, 2001) (Fig. 1), and the minor flavonoids, isotrifoliol and glisoflavanone, from the underground part of *G. uralensis* (Hatano *et al.*, 2000a).

Isoflavones

Isoflavonoid derivatives present in licorice include glabridin, galbrene, glabrone, shinpterocarpin, licoisoflavones A and B, formononetin, glyzarin, kumatakenin (Williamson, 2003). More recently, hispaglabridin A, hispaglabridin B, 4′-O-methylglabridin and 3′-hydroxy-4′-O-methylglabridin (De Simone *et al.*, 2001; Haraguchi, 2001) and glabroisoflavanone A and B glabroiso-flavanone B (Kinoshita *et al.*, 2005) have been found.

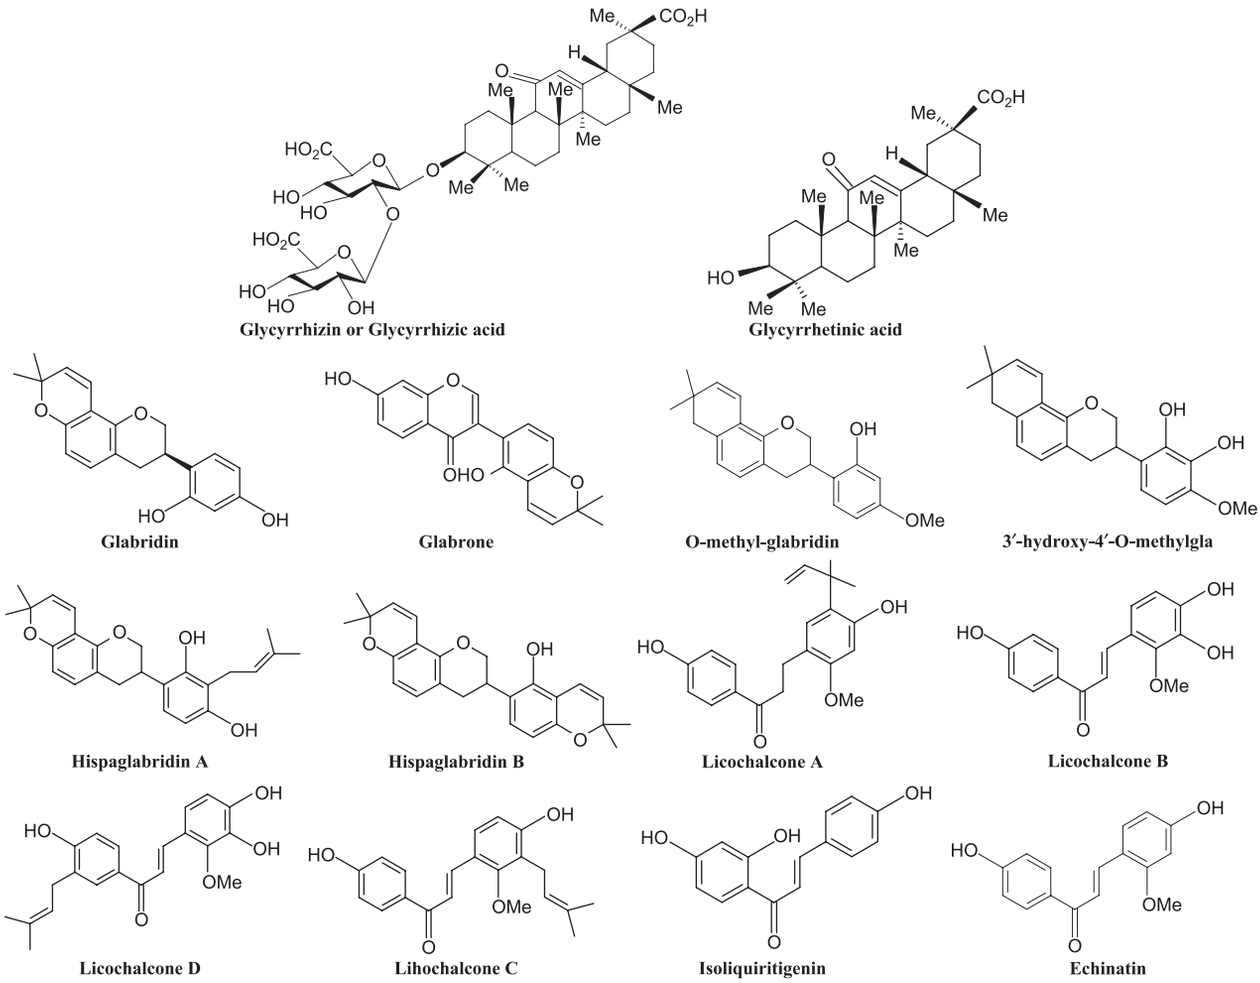

Figure 1. Chemical structure of some active components of Licochalcone C.

Coumarins

Coumarins present in *G. glabra* include liqcoumarin, glabrocoumarone A and B, herniarin, umbelliferone, glycyrin (Williamson, 2003), glycocoumarin, licofuranocoumarin, licopyranocoumarin (De Simone *et al.*, 2001; Haraguchi, 2001) and glabrocoumarin (Kinoshita *et al.*, 2005).

Stilbenoids

Four new dihydrostilbenes, dihydro-3,5-dihydroxy-4′-acetoxy-5′-isopentenylstilbene, dihydro-3,3′,4′-trihydroxy-5-O-isopentenyl-6-isopentenylstilbene, dihydro-3,5,3′-trihydroxy-4′-methoxystilbene and dihydro-3,3′-dihydroxy-5beta-d-O-glucopyranosyloxy-4′-methoxystilbene were isolated from the leaves of *G. glabra* grown in Sicily (Biondi *et al.*, 2005).

Miscellaneous compounds

G. glabra extract also contains fatty acids (C_2–C_{16}) and phenols (phenol, guaiacol), together with common saturated linear γ-lactones (C_6–C_{14}). A series of new 4-methyl-γ-lactones and 4-ethyl-γ-lactones in trace amounts has also been found (Näf and Jaquier, 2006). Asparagines, glucose, sucrose, starch, polysaccharides (arabinogalactants), sterols (β-sitosterol, dihydrostigmasterol) are also present (Hayashi *et al.*, 1998; Blumenthal *et al.*, 2000).

TRADITIONAL USES

Licorice has a long history of medicinal use in Europe and Asia. It is felt to be effective in the treatment of peptic ulcer disease, constipation, cough and other diseases which have been summarized in Table 1. As the table shows, it seems different parts of this herbs may be useful to treat some diseases.

PHARMACOLOGICAL EFFECTS

This part of review will deal with the pharmacological effects of the licorice and its bioactive components and their effects in treatment of diseases in different models of *in vivo* and *in vitro* studies. The pharmacology effects were divided into experimental and clinical studies in this review.

Table 1. Traditional use of different part of *G. glabra*

Extract	Traditional use
Fresh leaf (external)	Used for wounds (Dafni *et al.*, 1984)
Rhizome + root (infusion, oral)	Used to treat cystitis (Yarnell, 1997)
Root (oral)	Used to treat diabetes (Gray and Flatt, 1997)
Root (decoction, oral)	Used for cough, stomachache (Fujita *et al.*, 1995)
Aqueous extract of stem (oral)	Used for tuberculosis (Arseculeratne *et al.*, 1985)
Stem (oral)	Used for diabetes and as a diuretic (Rajurkar and Pardeshi, 1997)
Root (decoction, oral)	Used for kidney stones, lung ailment, ulcers (Dafni *et al.*, 1984)
Aqueous extract (oral)	Use in Addison's disease, gastric ulcers (Varshney *et al.*, 1983)
Aqueous extract (oral)	Used as anabolic and to improve the voice (Sircar, 1984)
Aqueous extract of root (oral)	Mild laxative (Armanini *et al.*, 2002)
Aqueous extract of rhizome (oral)	Contraceptive (Lee *et al.*, 1977)
Aqueous extract of rhizome + roots (oral)	Improve male sexual function (Nisteswar and Murthy, 1989)

EXPERIMENTAL STUDIES

Antiinflammatory activities

β-glycyhrritinic acid has shown antiinflammatory properties in different animal models (Capasso *et al.*, 1983; Amagaya *et al.*, 1984; Inoue *et al.*, 1989). β-Glycyhrritinic acid is the major metabolite of glycyrrhizin (Gumpricht *et al.*, 2005).

Two mechanisms have been suggested for the antiinflammatory effects of β-glycyhrritinic acid: First, it inhibits glucocorticoid metabolism and potentiates their effects. This potentiation was reported in skin and lung after coadministration of them with β-glycyhrritinic acid (Teelucksingh *et al.*, 1990; Schleimer, 1991). Since, β-glycyhrritinic acid is a potent inhibitor of 11β-hydroxysteroid hydroxygenase (Walker and Edwards, 1991), it causes an accumulation of glucocorticoids with antiinflammatory properties. Oral administration of β-glycyhrritinic acid or glycyrrhizin confirmed this result (MacKenzie *et al.*, 1990). Second, it inhibits classical complement pathway activation and its activity is dependent on its conformation (Kroes *et al.*, 1997). Thus, it is suggested that co-medication of it with hydrocortisone in the treatment of inflammatory lung disease will be useful (Schleimer, 1991).

Glycyrrhizin inhibited reactive oxygen species (ROS) generation by neutrophils which are the potent mediator of tissue inflammation in the *in vitro* study. It was thought that one of its antiinflammatory effect was due to this inhibitory effect (Akamatsu *et al.*, 1991; Wang and Nixon, 2001). Also, the generation of reactive oxygen species was also suppressed by glabridin treatment in RAW 264.7 cells (Jong *et al.*, 2005).

G. glabra and glyderinine, a derivative of glycyrrhizic acid, showed an antiinflammatory effect (Azimov *et al.*, 1988; Tokiwa *et al.*, 2004). It also reduced myocardial inflammatory edema in experimental myocardial damage (Zakirov *et al.*, 1999). In addition, glabridin and lichochalocone A have shown an antiinflammatory effect in *in vivo* studies (Furuhashi *et al.*, 2005; Jong *et al.*, 2005).

Glycyrrhetinic acid did not inhibit either cyclooxygenase 1 or 2 catalysed prostaglandin biosynthesis with an IC_{50} value of 425 μM in an *in vitro* study (Perera *et al.*, 2001). However, in another study *G. radix* was believed to be involved in COX-2 inhibition (Kase *et al.*, 1998). Furthermore, in this paper *G. radix* increased corticosterone levels in rats. Also, glycyrrhizin and glycyrrhetinic acid are known to inhibit phospholipase A_2 (Kase *et al.*, 1998). Recently, some derivatives of glycyrrhetinic acid have shown their inhibitory activity against interleukin-1b (IL-1b)-induced prostaglandin E2 (PGE2) production in normal human dermal fibroblasts (NHDF) (Tsukahara *et al.*, 2005).

Antimicrobial and antiviral activities

The methanol extract of aerial parts of *G. glabra* showed antibacterial activity against several kinds of bacteria (Sabahi *et al.*, 1987). Several flavonoids with C5 aliphatic residues were isolated as the effective constituents of licorice against methicillin-resistant *Staphylococcus aureus* (MRSA) and restored the effects of oxacillin and β-lactam antibiotic against MRSA (Hatano *et al.*, 2000b, 2005). Glabridin, glabrene and licochalcone A exhibited antimicrobial activity against *Helicobacter pylori in vitro* (Fukai *et al.*, 2002a, 2002b). The ether–water extracts of *G. glabra* were found to have effective antibacterial activity against all the five bacteria, *E. coli*, *B. subtilis*, *E. aerogenes*, *K. pneumoniae* and *S. aureus* (Onkarappa *et al.*, 2005). Glycyrrhizol A and 6, 8-diisoprenyl-5, 7, 4′-trihydroxyisoflavone from the root of *G. uralensis* exhibited potent antibacterial activity against *Streptococcus mutans* with minimum inhibitory concentrations of 1 and 2 μg/mL, respectively (He *et al.*, 2006).

Glycyrrhizic acid inhibits the replication of several viruses *in vitro* (Table 2) and some mechanisms have been found for the antiviral effects of glycyrrhizin (Van Rossum *et al.*, 1998; Cohen, 2005). In another study glycyrrhizic acid induced apoptosis of primary effusion lymphoma (PEL) cells that were transformed by Kaposi sarcoma-associated herpesvirus (KSHV) and terminated latent infection in B lymphocytes (Curreli *et al.*, 2005).

Two coumarins of *G. glabra*, glycocoumarin and licopyranocoumarin, were able to inhibit giant cell formation in HIV-infected cell cultures without any cytotoxicity (Hatano *et al.*, 1988; De Simone *et al.*, 2001) (Fig. 2). Also, Hatano *et al.* (1988) showed that lichochalcone A had anti-HIV activity (Hatano *et al.*, 1988).

Table 2. Antiviral effects of glycyrrhizin in *in vitro* study

Virus	Reference
Epstein-Barr virus (EBV)	Lin, 2003
Herpes simplex virus	Pompei *et al.*, 1979
Hepatitis A virus (HAV)	Crance *et al.*, 1990
Hepatitis B virus (HBV)	Takahara *et al.*, 1994; Sato *et al.*,1996
Hepatitis C virus (HCV)	Van Rossum *et al.*, 1998
Human cytomegalovirus (CMV)	Numazaki *et al.*, 1994
Human immunodeficiency virus (HIV)	Ito *et al.*, 1988
Influenza virus	Utsunomiya *et al.*, 1997
SARS coronavirus	Cinatl *et al.*, 2003
Varicella zoster virus (VZV)	Baba and Shigeta, 1987

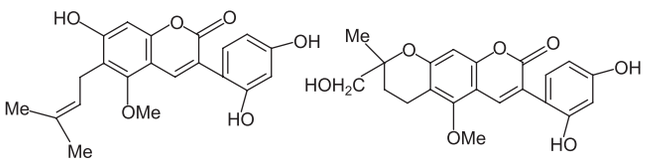

Figure 2. Anti-HIV coumarins isolated from *G. glabra.*

Antiprotozoal activities

Chinese licorice roots which can be obtained from the three species of *Glycyrrhiza* genus, *G. glabra*, *G. uralensis* or *G. inflata*, were found to potentially inhibit the growth of *Plasmodium. falciparum* and *Leishmania donovani* in *in vitro* studies (Christensen *et al.*, 1994; Christensen and Kharazmi, 2001). Chalcones such as licochalcone A from Chinese licorice roots are known to possess antiplasmodial activity with IC_{50} values between 4.5 and 0.6 mg/mL (Chen *et al.*, 1994b; Jenett-Siems *et al.*, 1999). Also, chalcones have a potent antileishmanial activity and might be developed into a new class of antileishmanial drugs (Chen *et al.*, 1993; Chen, 1994a). It was found that chalcones, such as lichochalcone A, alter the ultrastructure of the parasite mitochondria and inhibit their function by selectively inhibiting fumarate reductase (FRD) in the respiratory chain of the parasite (Zhai *et al.*, 1995; Chen *et al.*, 2001).

Antioxidative activities

The constituents of *G. inflata*, licochalcone A, B, C, D and echinatin, were effective in preventing microsomal lipid peroxidation induced by Fe (III)-ADP/NADPH and licochalcone B, D showed potent antioxidative and superoxide scavenging activities (Haraguchi *et al.*, 1998). Furthermore, the isoflavone derivatives of *G. glabra* such as glabridin inhibited lipid peroxidation in rat liver microsomes and protected mitochondrial functions from oxidative stresses (Haraguchi *et al.*, 2000). Hispaglabridin A, especially, showed a potent antioxidative activity against peroxidation induced by Fe-ascorbate (Haraguchi, 2001).

Moreover, glabridin, an isoflavan of *G. glabra*, was a potent antioxidant toward LDL oxidation in *in vitro* and *in vivo* studies (Fuhrman *et al.*, 1997; Vaya *et al.*, 1997; Belinky *et al.*, 1998a). The consumption of licorice or glabridin by atherosclerotic apolipoprotein E-deficient (E^0) mice caused a significant reduction not only in their LDL oxidation but also in the development of atherosclerotic lesions (Fuhrman *et al.*, 1997; Rosenblat *et al.*, 1999). It seems that glabridin may possess this property by two mechanisms: first it binds to the LDL and substantially protects its oxidation (Fuhrman *et al.*, 1997; Belinky *et al.*, 1998a). The hydroxyl groups on the B ring of glabridin were found to be most important for its antioxidative properties (Belinky *et al.*, 1998b). Second it accumulates in cells such as macrophages, causing a reduction of cellular oxidative stress by reducing NADPH oxidase activation and increasing cellular glutathione (GSH) (Rosenblat *et al.*, 1999, 2002). In addition, other constituents of *G. glabra* such as isoflavones hispaglabridin A, hispaglabridin B and 4′-O-methylglabridin, the two chalcones, isoprenylchalcone derivative and isoliquiritigenin were antioxidants against LDL oxidation (Vaya *et al.*, 1997).

Hepatoprotective studies

In an *in vitro* study, glycyrrhizin was hepatoprotective, probably by preventing changes in cell membrane permeability (Nakamura *et al.*, 1985). Nevertheless, it was suggested that glycyrrheitinic acid is a better hepatoprotective drug than glycyrrhizin in *in vitro* study (Nose *et al.*, 1994). This observation is in keeping with the protective effects of glycyrrhetinic acid against the carbon tetrachloride-induced hepatotoxicity and retrorsine-induced liver damage, respectively, in mice and rats (Lin *et al.*, 1999; Jeong *et al.*, 2002). Furthermore, in a hepatocyte model of cholestatic liver injury, glycyrrhizin exhibited pro-apoptotic properties, whereas glycyrrheitinic acid is a potent inhibitor of bile acid-induced apoptosis and necrosis (Gumpricht *et al.*, 2005). Some hepatoprotective effects of glycyrrhizin have been summarized in Table 3.

Antitumor activities

The aqueous extract of *G. glabra* inhibits the *in vivo* and *in vitro* proliferation of Ehrlich ascites tumor cells and inhibits angiogenesis in *in vivo* assay, peritoneal and chorioallantoic membrane assays (Sheela *et al.*, 2006). Also, the ethanol extract of *G. uralensis* root induced apoptosis and G1 cell cycle arrest in MCF-7 human breast cancer cells (Jo *et al.*, 2005). On the other hand, there are many studies about the anticancer effects of several derivatives of its components both

Table 3. Cytoprotective effects of glycyrrhizin in the liver

Study	Method	Mechanism
In vitro		
Rat hepatocytes	Incubation with anti-liver cell membrane antibody + complement	Deceased release of AST and inhibition PLA_2 (Shiki *et al.*, 1992)
Rat hepatocytes	CCl_4-induced hepatotoxicity	Deceased LDH and glutamic oxaloacetic transaminase (Nakamura *et al.*, 1985)
Rat hepatocytes	Acetaminophen or D-galactosamine induced liver injury	Increased survival rate of the hepatocyte culture (Nacagiri *et al.*, 2003)
In vivo		
Rat liver	Ischemia-reperfusion damage	Suppressed the elevation lipid peroxides, AST, ALT, LDH and decreased morphological damage (Nagai *et al.*, 1991)
Rat liver	Retrorsine-induced liver damage	Normalized serum levels of transaminase Lin *et al.*, 1999)
Rat liver	Thioacethamide-induced liver damage	Normalized serum aminotransferases, alkaline phosphatase and bilirubin (Asgary *et al.*, 2005)

Aspartate aminotransferase (AST), alanine aminotrasferase (ALT), lactate dehydrogenase (LDH), phospholipase A_2 (PLA_2), carbon tetrachloride (CCl_4).

in *in vivo* and *in vitro* studies. For more detail see Table 4.

Glycyrrhetinic acid could also trigger the pro-apoptotic pathway by inducing mitochondrial permeability transition and this property may be useful for inducing apoptosis of tumor cells (Salvi *et al.*, 2003; Fiore *et al.*, 2004). Recently, licochalcone E, a new retrochalcone from the roots of *G. inflata*, exhibited the most potent cytotoxic effect compared with the known antitumor agents, licochalcone A and isoliquiritigenin (Yoon *et al.*, 2005).

Central nervous system studies

Glabridin inhibited serotonin reuptake (Ofir *et al.*, 2003). In addition, recently, the aqueous extract of *G. glabra* L. showed antidepressant activity in both the forced swim test (FST) and tail suspension test (TST) in mice (Dhingra and Sharma, 2005). The ethanol extract of *G. glabra* had an anticonvulsant effect in PTZ and lithium-pilocarpine-induced convulsion models (Ambawade *et al.*, 2002). Also, the aqueous extract of *G. glabra* showed memory enhancing effects in the plus-maze and passive avoidance paradigm (Dhingra *et al.*, 2004). Moreover, chronic administration of the extract of *G. glabra* in both low and high doses induced correction of the passive avoidance performance in ovariectomized female rats (Fedotova *et al.*, 2005). Combined treatment with licorice root and vibration resulted in increased succinate dehydrogenase (SDH) activity in different parts of the brain, improved brain energy supply and ameliorated the effect of vibration (Oganisyan *et al.*, 2005). In addition, isoliquiritigenin showed protective effects in cerebral ischemia-reperfusion injury in rats (Zhan and Yang, 2006).

Carbenoxolone has shown anticonvulsant, sedative and muscle relaxant activities in mice and in genetically epilepsy prone rats (GEPRs) (Hosseinzadeh and Nassiri Asl, 2003; Gareri *et al.*, 2004). Also, it was able to suppress the generation of superoxide anions and hydrogen peroxide in macrophages and it also showed protective effects in the skeletal muscle and hippocampus against acute ischemic-reperfusion effects in rats (Suzuki *et al.*, 1983; Hosseinzadeh *et al.*, 2005a). In addition it could decrease the learning performances of rats in a spatial memory task (Hosseinzadeh *et al.*, 2005b).

Cardiovascular studies

Licorice showed an antiplatelet aggregation effect (Tawata *et al.*, 1992; Yu *et al.*, 2005). In other experiments, glycyrrhizin has been identified as a thrombin inhibitor in *in vitro* and *in vivo* studies and it was believed that glycyrrhizin might be used as a model for searching new antithrombotic drugs (Francischetti *et al.*, 1997; Mendes-Silva *et al.*, 2003). Also, *G. glabra* accelerated the metabolism of cells in the bone marrow erythroid stem and increased the animal's resistance to stress (Adamyan *et al.*, 2005).

Isoliquiritigenin, an active component of licorice, is reported to have a vasorelaxant effect (Yu and Kuo, 1995). It could also able to decrease tube formation in vascular endothelial cells. Thus, the anti-angiogenic effect of licorice extract depended on the anti-tube formation effect of isoliquiritin (Kobayashi *et al.*, 1995). On the other hand, as for the estrogen-like activities of glabridin in *in vivo* and *in vitro* studies, it was demonstrated that it could modulate vascular injury and atherogenesis. Therefore, it is suggested for the prevention of cardiovascular diseases in post-menopausal women (Somjen *et al.*, 2004b).

Immunological studies

Several immunomodulatory activities have been attributed to glycyrrhizin and glycyrrhetinic acid (Ohuchi *et al.*, 1981; Kobayashi *et al.*, 1993; Zhang *et al.*, 1993; Kondo and Takano, 1994; Raphael and Kuttan, 2003). The same results were seen with lichochalchone A and some analogues which showed immunomodulatory effects (Barfod *et al.*, 2002).

On the other hand, glycyrrhizin selectively activated extrathymic T cells in the liver and in human T cell

Table 4. Anticancer effects of some active component of licorice

Compound	Method	Effects
Lichochalcone A	MCF-7 breast, HL-60 leukemia and PC-3 prostate cancer cell lines	Antitumor activity, induced apoptosis by modulating bcl-2 protein expression (Rafi *et al.*, 2000, 2002; Fu *et al.*, 2004)
	DMBA-initiated and TPA-promoted skin papilloma in mice	Antitumor promoting activity by preventing TPA to bind to the membrane receptors (Kitagawa *et al.*, 1986; Shibata *et al.*, 1991)
	TPA-promoted $^{32}P_i$-incorporation into phospholipids of HeLa cells	Inhibitory effect (Shibata *et al.*, 1991)
Glycyrrhetinic acid (GA)	Tumor promoted by TPA *in vivo* study	Antitumor-promoting activity (Kitagawa *et al.*, 1986)
Glycyrrhizic acid (aqueous extract of licorice root)	AFB1-induced cytotoxicity in human HepG2 cells	Protective effect and prevent chemical-induced carcinogenicity by inhibition the activation of hepatotoxic metabolites (Chan *et al.*, 2003)
Isoliquiritigenin (ILG)	AOM-treated ddY mice	Inhibited induction of ACF and colon carcinoma development (Baba *et al.*, 2002; Takahashi *et al.*, 2004)
	DMBA-induced skin carcinogenesis in mice	Inhibited epidermal ODC and suppressed DMBA effects (Yamamoto *et al.*, 1991)
	B16 melanoma 4A5 cells	Induced cell death and promotion of Bax expression (Iwashita, *et al.*, 2000)
	MGC-803 gastric cancer cells	Antiproliferative activity (Ma *et al.*, 2001)
	MCF-7 breast cancer cells	Antiproliferative activity (Maggiolini *et al.*, 2002)
	DU 145 and LNCaP prostate cancer cells	Antiproliferative activity (Kanazawa *et al.*, 2003)
	MLL(rat) and DU145 (human) prostate cancer cells	Inhibited cell growth and decreased cell number, induced apoptosis (Jung *et al.*, 2006)
	A549 lung cancer cells	Antiproliferative activity, enhanced expression of $p21^{CIP1/WAF1}$ expression (Hsu *et al.*, 2004; li *et al.*, 2004)
	Pulmonary metastasis model of murine renal cell carcinoma cell line (Renca)	Reduced pulmonary metastasis (Yamazaki *et al.*, 2002)
	Hep G2	Induced apoptotic cell death by inhibiting the NF-kappaB survival-signaling pathway (Hsu *et al.*, 2005)
Glabridin	In the human breast cell line	Antiproliferative effects (Tamir *et al.*, 2000)
Dibenzoylmethane (DBM)	DMBA-induced mammary tumor in Sencar mice	Inhibited formation, proliferation of total DMBA-DNA adducts in mammary gland (Lin *et al.*, 2001)
	LNCaP, DU145, and PC-3 prostate carcinoma cell lines	Cytostatic effect with deregulation cell cycle (Jackson *et al.*, 2002)

Dimethylbenz [*a*] anthracene (DMBA), 12-O-tetradecanoylphorbol 13-acetate (TPA), aflatoxin B1 (AFB1), hepatoma cell line (HepG2), azoxymethane (AOM), aberrant crypt foci (ACF), ornithine decarboxylase (ODC), MAT-LyLu (MLL), 7,12-dimethylbenz[a]anthracene (DMBA).

lines and glycyrrhizic acid enhanced Fas-mediated apoptosis without alteration of caspase-3-like activity (Kimura *et al.*, 1992; Ishiwata *et al.*, 1999). Glycyrrhizin also improved the impaired resistance of thermally injured mice to herpes virus infection (Utsunomiya *et al.*, 1995). Moreover, glycyrrhetinic acid was an inducer of type 2 antagonistic CD41 T cells in *in vivo* and *in vitro* studies (Kobayashi *et al.*, 1993; Utsunomiya *et al.*, 1995; Nakajima *et al.*, 1996). It improved the resistance of mice infected with LP-BM5 murine leukemia virus (MAIDS) mice to *Candida albicans* infection (Utsunomiya *et al.*, 2000). Also, it stimulated macrophage-derived NO production, and was able to up-regulate iNOS expression through nuclear factor *k*B (NF- *k*B) transactivation in murine macrophages (Jeong and Kim, 2002). Both of them could induce interferon activity and augment natural killer cell activity and in this study glycyrrhizin was superior to glycyrrhetinic acid in inducing interferon (Abe *et al.*, 1982). It also has inhibitory effects on TNF-alpha-induced IL-8 production in intestinal epithelial cells (Kang *et al.*, 2005).

In addition, there are some studies on the immunomodulatory effects of polysaccharide fractions obtained from shoots of *G. glabra* and hairy roots of *G. uralensis in vitro* (Nose *et al.*, 1998). GR-2IIa and GR-2IIb, two isolated acidic polysaccharides of *G. uralensis*, have shown anticomplementary activity. Also, GR-2IIc had both anticomplementary activity and mitogenic activity (Zhao *et al.*, 1991; Yamada *et al.*, 1992; Kiyohara *et al.*, 1996). Recently, the haemolytic activities of *G. uralensis* saponins (GLS) and its adjuvant potentials against ovalbumin (OVA) were established in mice (Sun and Pan, 2006).

Renal studies

Glabridin showed an antinephritis effect in the mouse glomerular disease model (Fukai *et al.* 2003). Also, glycyrrhizin could ameliorate renal defects in gentamicin-induced acute renal failure in rats (Sohn *et al.*, 2003). Also, the extract of *G. radix* could protect the kidneys against peroxynitrite ($ONOO^-$)-induced oxidative stress

DOI: 10.1002/ptr

in vivo through scavenging $ONOO^-$ and/or its precursor NO (Yokozawa *et al.*, 2005).

Cytotoxic activities

Sixty nine compounds of *Glycyrrhiza* phenols showed an inhibitory activity on the growth of *Bacillus subtilis* H17 and M45 and some of them, such as isoliquiritigenin, were positive in the rec-assay (Fukai *et al.*, 1998).

Respiratory studies

Recently in one study, *G. radix* produced a persistent antitussive effect in the guinea-pig, suggesting that liquiritin apioside, a main antitussive component, plays an important role in the earlier phase, while liquiritigenin and liquiritin play an important role in the late phase (Kamei *et al.*, 2005). This result is keeping with the previous antitussive effects of licorice.

Effects on gap junction channels

Glycyrrhitinic acid and its derivatives were shown to inhibit gap junction channels (Davidson and Baumgarten, 1988). The inhibitory effects of 18β-glycyrrhetinic acid on gap junction channels of arteriolar smooth muscle, endothelial cells, renal pelvis, ureter and mesenteric small arteries were studied (Yamamoto *et al.*, 1998; Santicioli and Maggi, 2000; Matchkov *et al.*, 2004).

Endocrinological studies

Some effects of licorice on the endocrine system in *in vitro* and *in vivo* studies are summarized in Table 5. It seems that this herb acts on the metabolism of steroids with different mechanisms.

Other studies

In endocrinological studies, glabridin increased the growth of mouse osteoblastic (MC3T3-E1) and human cell lines (Somjen *et al.*, 2004a; Choi, 2005). The alcohol extract of licorice reduced the glucose levels of genetically diabetic KK-A^y mice (Kuroda *et al.*, 2003).

Table 5. The effects of licorice on the function of different enzymes

Enzyme	Effects
11β-HSD Type 1	Inhibition (Jellinck *et al.*, 1993; Hult *et al.*, 1998;
11β-HSD Type 2	Inhibition (Monder *et al.*, 1989; Ferrari *et al.*, 2001; Palmero *et al.*, 2004)
3HSD	Inhibition (Latif *et al.*, 1990)
17HSD	Inhibition (Armanini *et al.*, 2003)
17-20 lyase	Inhibition (Armanini *et al.*, 2003)
Aromatase	Increase (Sakamoto and Wakabayashi, 1988)
5α-Reductase	Increase (Latif *et al.*, 1990; Fugh-Berman and Ernst, 2001)

In addition, dermatological studies showed that three flavonoids of licorice, licuraside, isoliquiritin and licochalcone A, have high potential for studying depigmenting agents by inhibiting tyrosinase (Fu *et al.*, 2005). The same results were reported for glycyrrhisoflavone and glyasperin C (Kim *et al.*, 2005).

CLINICAL STUDIES

Gastrointestinal effects

It was shown that oral licorice in a combination product could heal ulcers as effectively as an H2 blocker (Kassir, 1985; Aly *et al.*, 2005). Glycyrrhizinic acid, a major component of licorice, has antiulcer properties, it seems by raising the local concentration of prostaglandins that promote mucous secretion and cell proliferation in the stomach, leading to healing of ulcers in experimental studies (Van Marle *et al.*, 1981; Baker, 1994).

Carbenoxolone, a hemisuccinate derivative of 18β-glycyrrhetinic acid, and enoxolone are two chemical synthetic derivatives of licorice which have been used in clinical therapies (Fig. 3). Enoxolone, an analogue of carbenoxolone, has been used for the treatment of peptic ulcer disease and other GIT disorders, skin disorders, mouth and throat disorders (Sweetman, 2005). Carbenoxolone has been used for peptic ulcer disease, gastro-oesophageal reflux and also it has been used for the symptomatic management of mouth ulceration as a gel or mouthwash (Sweetman, 2005).

Anticancer effects

Licorice root has been identified by the National Cancer Institute as possessing cancer-preventive properties (Craig, 1999; Wang and Nixon, 2001). It has been used among patients with prostate cancer as an ingredient of PC-SPES, a commercially available combination of eight herbs (DiPaola *et al.*, 1998).

Antioxidative effects

G. glabra extracts showed great antioxidant and free radical scavenging activities in topical formulations and may be used in topical formulations in order to protect the skin against damage caused by free radical and reactive oxygen species (Di Mambro and Fonseca, 2005).

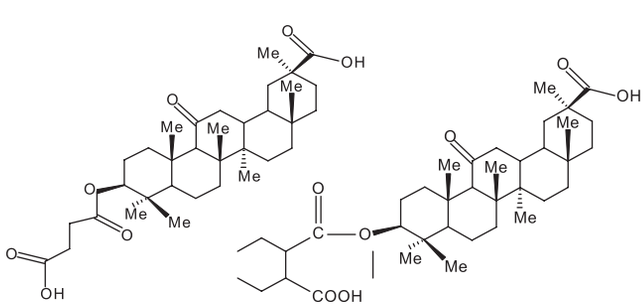

Figure 3. Chemical structures of carbenoxolone and enoxolone.

Antiviral and hepatoprotective effects

In the world, especially in Asia, glycyrrhizic acid is used intravenously for the treatment of chronic hepatitis B and C and its preparation under the name of Stronger Neo-Minophagen C (SNMC) decreased aminotransferase levels in patients with chronic hepatitis in multiple double-blind studies (Van Rossum *et al.*, 1999; Iino *et al.*, 2001; Zhang and Wang, 2002). It is suggested that glycyrrhizin has a preventive effect on the development of hepatocellular carcinoma (HCC) in patients with HCV-associated chronic hepatitis (Arase *et al.*, 1997; Miyakawa and Iino, 2001).

Licorice has been reported to have a direct hepatoprotective effect (Luper, 1999; Leung *et al.*, 2003). Glycyrrhizin, its major component, is often used to treat patients with chronic liver damage who do not receive or respond to interferon (IFN) therapy (Okuno *et al.*, 2001). Stronger Neo-Minophagen C® (SNMC), containing 2 mg/mL of glycyrrhizin, has been used clinically as an antihepatitis agent (Shibata, 2000).

Dermatological studies

G. glabra L. has been used in herbal medicine for skin eruptions, including dermatitis, eczema, pruritus and cysts (Saeedi *et al.*, 2003). In this section the various studies of licorice on the skin are summarized in Table 6.

Recently glycyrrhizin treatment has showed protective effects against UVB-irradiated human melanoma cells (Rossi *et al.*, 2005). Moreover, licorice extract and its active component, glycyrrhizic acid has been described as effective skin whitening effects (Smith, 1999). The group of Briganti classified liquiritin as a skin turnover accelerator (Briganti *et al.*, 2003). However, it was suggested that liquiritin causes depigmentation by two mechanisms: first, via melanin dispersion by means of the pyran ring of its flavonoidal nucleus; second the acceleration of epidermal renewal (Amer and Metwalli, 2000). Concerning the mechanisms of glabridin on melanogenesis and inflammation, it has been shown that it inhibits the tyrosinase activity of melanocytes and as a result, it seems that hydroquinone will be replaced by licorice extract in a new preparation for dermal melasma (Piamphongsant, 1998). However, in a few cases, allergic dermatitis can develop to oil soluble licorice extracts (Nishioka and Seguchi, 1999).

Table 6. Licorice and its components in skin therapies

Compound	Treatment
Licorice (topical gel 2%)	Atopic dermatitis (Saeedi *et al.*, 2003)
GA	Inflammatory dermatoses (Cohen and Heidary, 2004)
Deglycyrrhizinated licorice and carbenoxolone (topical)	Recurrent aphthus stomatitis (RAS) (Scully *et al.*, 2002)
Liquiritin (topical 2%)	Hyperpigmentation (in patient with bilateral and symmetrical idiopathic epidermal melasma) (Amer and Metwalli, 2000)
Glabridin	Melanogenesis, inflammation (Yokota *et al.*, 1998; Petit and Pierard, 2003; Halder and Richards, 2004)

Glycyrrhetinic acid (GA).

Endocrinological effects

Glycyrrhiza root has been shown to decrease circulating levels of testosterone in men and women (Armanini *et al.*, 1999, 2002; Rafi *et al.*, 2002; Armanini *et al.*, 2004). But it was not able to reduce salivary testosterone in men significantly (Josephs *et al.*, 2001). Moreover, it induced regular ovulation and pregnancy in infertile hyperandrogenic patients (Yaginuma *et al.*, 1982).

On the other hand, isoliquiritigenin (ILC), glabrene and glabridin are phytoestrogens. ILC and glabrene can bind to the human estrogen receptor (ER) with higher affinity than glabridin. It was suggested that isoflavenes may serve as natural estrogen agonists in preventing the symptoms and diseases associated with estrogen deficiency (Tamir *et al.*, 2000, 2001). In some traditional Chinese medicine preparations, the root of *G. glabra* is used for treatment menopause-related symptoms. But there are no clinical data regarding its safety or efficacy for treating hot flashes (Santoro *et al.*, 2004).

Moreover, the activity of 11β-HSD-2 potently is blocked *in vivo* and *in vitro* by glycyrrhetinic acid by two mechanisms, direct competitive inhibition and pretranslational inhibition (Ferrari *et al.*, 2001). It seems that this herb acts on the metabolism of steroids with different mechanisms. The consumption of licorice extract and glycyrrhetinic acid could decrease body fat mass in humans and a possible mechanism seems to be by inhibiting 11β-HSD1 at the level of fat cells (Armanini *et al.*, 2005).

Respiratory diseases

Licorice has been used as a cough-relieving medicinal herb from ancient times. It seems that mucilage present in it or secretion produced under the influence of the active substances covers the oral and throat mucosa soothing its irritability and relieving dry cough (Ody, 2000; Puodziuniene *et al.*, 2005).

Other effects

Ammonium glycyrrhizate (from licorice root) is used in toothpastes, mouth rinses and other products for the control of periodontal disease (Goldie, 2005). The extract of *G. glabra* in combination with other herbs, such as ImmunoGuard®, has been effective for the prophylactic management and treatment of patients with Familial Mediterranean Fever (FMF) (Amaryan *et al.*, 2003).

INDUSTRIAL USES

Commercially, licorice is added to chewing gum, chocolate candy, cigarettes, smoking mixtures, chewing tobacco and snuff as sweetening agents (Tyler *et al.*, 1988; De Klerk *et al.*, 1997) and as a depigmentation

Table 7. Products containing considerable amounts of glycyrrhizinic acid (De Klerk *et al.*, 1997)

Confectionery	Licorice sticks, bricks, cakes, toffee, pipes, bars, balls, tubes, Catherine wheels, pastilles and allsorts
	Sorbits chewing gum
	Stimorol chewing gum
Health products	Licorice flavored diet gum
	Throat pearls
	Licorice flavored cough mixtures
	Herbal cough mixtures
	Licorice tea
All types of licorice root	Russian, Iranian, Chinese, Turkish, Afghan and unknown origin
	Chewing tobacco
	Alcoholic drinks

agent in cosmetics (Nomura *et al.*, 2002). Also, licorice is frequently employed to mask the taste of bitter drugs such as aloe, quinine and others. The surfactant property of the saponins may also facilitate the absorption of poorly absorbed drugs, such as the anthraquinone glycosides (Tyler *et al.*, 1988). Some of the products which have glycyrrhizinic acid are summarized in Table 7 (De Klerk *et al.*, 1997).

SIDE EFFECTS AND TOXICITY

Large amounts of licorice may result in severe hypertension, hypokalemia and other signs of mineralocorticoid excess. This hypertension is caused by decreased 11β-HSD2 activity. This enzyme is responsible for the renal conversion of cortisol to cortisone. Thus, licorice leads to activation of renal mineralocorticoid receptors by cortisol, resulting in a state of apparent mineralocorticoid excess and suppression of the rennin angiotensin system (Conn *et al.*, 1968, Stewart *et al.*, 1990; Van Uum, 2005). Some side effects due to the consumption of licorice have been reported by different groups and are summarized in Table 8.

Carmines *et al.* (2005) reported that adding licorice extract to cigarette tobacco at levels of ≤5% (about 0.269% glycyrrhizic acid) did not significantly alter the toxicity of smoke. Also, in this paper, it was mentioned that licorice is not a teratogen or genotoxic (Carmines *et al.*, 2005). In another study, the toxicity of licorice extract was shown in the liver of Black molly fish (Radhakrishnan *et al.*, 2005).

PHARMACOKINETICS

After oral administration, glycyrrhizin is metabolized to glycyrrhetinic acid by intestinal bacteria which contain β-D-glucuronidase (Hattori *et al.*, 1985). Furthermore, intravenously administered glycyrrhizin is metabolized in the liver by lysosomal β-D-glucuronidase to 3-mono-glucuronide glycyrrhetinic acid. This metabolite is excreted with bile into the intestine, where it is metabolized by bacteria into glycyrrhetinic acid, which can be reabsorbed (Akao *et al.*, 1991) (Fig. 4).

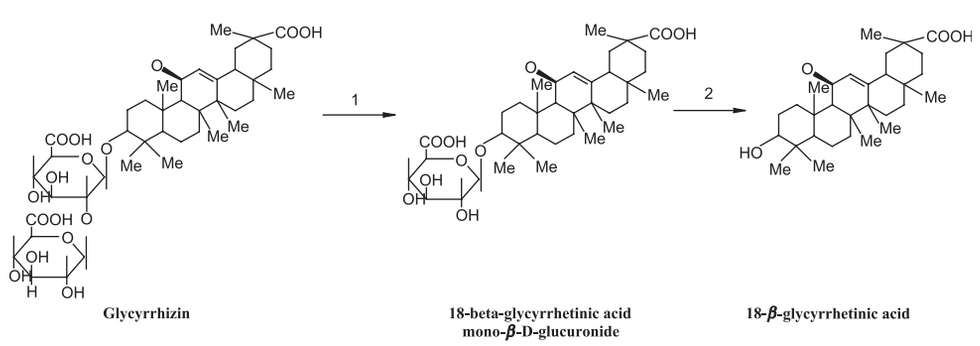

Figure 4. Metabolism of glycyhrrizin in the liver (1) by lysosomal β-D-glucuronidase to 3-mono-glucuronide glycyrrhetinic acid and then in the intestine (2) by bacteria β-D-glucuronidase after intravenous administration (Akao *et al.*, 1991).

DOI: 10.1002/ptr

Other components of the extract could affect the pharmacokinetics of glycyrrhizin (G) and glycyrrhetic acid (GA), a main metabolite of G. After administration of aqueous licorice root extract (LE) to rats and humans, G and GA levels were lower compared with G alone and the pharmacokinetic curves showed significant differences in the areas under the plasma-time curve (AUC), C_{max}, and T_{max} parameters. Also, the data obtained from urine samples confirmed a reduced bioavailability of G present in LE compared with pure G. Interaction between the G constituent and other components in LE during intestinal absorption was mentioned. Thus, modified bioavailability could explain the various clinical adverse effects resulting from the chronic oral administration of G alone as opposed to LE (Cantelli-Forti *et al.*, 1994). However, it seems that the pharmacokinetics differ in other species. In another study the AUCs of G and GA after oral administration of LE were significantly higher than those after pure G in rabbits and the bioavailabilities of G and GA were significantly better from licorice than from pure G in rabbits, but the presystemic metabolism of pure G in the rabbit is rather different from that in rat, pig and human (Hou *et al.*, 2005). It was shown that the pharmacokinetics of G is nonlinear. After bolus intravenous administration at a dose of 20, 50, or 100 mg/kg in rat, the decline in the concentration of G in plasma, was generally biexponential at each dose, but the terminal disposition became much slower as the dose was increased. In addition, the apparent total body clearance decreased significantly with increases in the dose. But the apparent distribution volume after intravenous administration was unaffected by the dose (Tsai *et al.*, 1992). Administration of different oral doses of 18-beta-glycyrrhetinic acid (β-GRA) in healthy volunteers showed a biphasic decay of the plasma concentration-time curve at doses >500 mg. The peak plasma concentration and the AUC increased with increasing β-GRA doses. Urinary elimination of β-GRA and its glucuronides over 24 h was less than 1% of the dose administered. The data based on single dose kinetic analysis revealed that after multiple doses of 1.5 g β-GRA/day, 11 beta-hydroxysteroid dehydrogenase (11 beta-HSD) might be constantly inhibited, whereas at daily doses of 500 mg or less, such an inhibition might occur only transiently (Krahenbuhl *et al.*, 1994).

Administration intravenously of G to an animal model of liver disease (D-galactosamine-intoxicated (GAL) rat), significantly decreased the apparent volume of distribution (V_{dss}) and the total body clearance (CL_{total}) than those in normal rats. When G was administered orally, the AUC, the mean residence time (MRT) and the time to reach the maximum plasma concentration (T_{max}) for G were higher, but the maximum plasma concentration (C_{pmax}) in GAL rats was lower than that in normal rats. But, the bioavailability of G was not significantly changed. Also, the AUC for GA, after oral administration of G was higher in GAL rats than in normal rats, although there was no significant difference in MRT or T_{max}, C_{pmax} or the bioavailability for GA between GAL and normal rats. However, the changes in the absorption rate and reduction of the hepatic elimination rates in GAL rats could explain these differences (Wang *et al.*, 1996). GA has a large volume of distribution, a long biological half-life, and undergoes substantial enterohepatic circulation (Tyler *et al.*, 1988). Thus, large doses of KCl supplementation for weeks are necessary because of the long half-life of glycyrrhetic acid (Van Den Bosch *et al.*, 2005).

In another study, liquiritin apioside showed a peak plasma concentration 15 min after administration in guinea-pigs, which gradually decreased and was almost undetectable 4 h after administration. Liquiritigenin, an aglycone of liquiritin apioside, appeared in the plasma 2 h after the administration of liquiritin apioside and remained for more than 6 h after administration. The plasma concentration of unchanged liquiritigenin was observed 15 min after administration and then gradually increased for more than 6 h after administration (Kamei *et al.*, 2005).

Glycyrrhizin, genistein, glycyrrhisoflavone, glicoricone, licofuranone, licopyranocoumarin licocoumarone and other licorice constituents were found to inhibit monoamine oxidase (MAO) *in vitro* (Hatano *et al.*, 1991b). However, the clinical significance of this is not known and not all these compounds are found in all species.

Based on the phenolic constituent of licorice sp, they were classified into three types A, B, C:

Type A: roots and rhizomes of *G. uralensis* containing licopyranocoumarin, glycycoumarin and/or licocoumarone, which were not found in *G. glabra* and *G. inflata*. Type B: *G. glabra*, containing glabridin and glabrene, which were not found in the samples of the other two species. Type C: *G. inflata*, containing licochalcones A and B, which were not found in the other two species.

Extracts of some licorice specimens of types A, B, and C inhibited 40–56% of xanthine oxidase activity. Extracts of some licorice specimens of types A and B also showed inhibitory effects on monoamine oxidase (44–64%) (Hatano *et al.*, 1991a).

DRUG INTERACTIONS

The extract of *G. uralensis* showed potent CYP3A4 inhibitory activity (Hu *et al.*, 1999; Budzinski *et al.*, 2000; Tsukamoto *et al.*, 2005). After bioassay purification, other components such as (3*R*)-vestitol, 4-hydroxyguaiacol apioglucoside, liquiritigenin 7, 4′-diglucoside, liquiritin apioside showed potent CYP3A4 inhibitory activities among them (Tsukamoto *et al.*, 2005). Glabridin was also found to inactivate the enzymatic activities of CYP 3A4 and 2B6 and competitively inhibited 2C9 (Kent *et al.*, 2002).

In other hands, prolonged intake of high LE or G doses may result in accelerated metabolism of coadministered drugs. Daily oral doses of LE or G for 1, 4 or 10 consecutive days in mice, were able significantly to induce hepatic CYP3A- and, to a lesser extent, 2B1- and 1A2-dependent activities, as well as 6-beta- (mainly associated to CYP3A), 2-alpha-, 6-alpha- (CYP2A1, 2B1), 7-alpha-, 16-alpha- (CYP2B9) and 16-beta-testosterone hydroxylase (TH) activities. Thus, the induction of cytochrome P450-dependent activities by long-term ingestion of licorice may have clinical consequences for patients taking drugs metabolized by the same CYP enzymes (Paolini *et al.*, 1998). But, high doses of LE and G could cause significant adverse effects. Thus, it seems that routine licorice consumers under CYP3A induction might therefore be predisposed to associated

Table 9. Some drug interaction due to consumption of licorice and its bioactive components

Licorice	Drug	Results of interaction
Gan Cao (*G. uralensis*)	Warfarin	Increase metabolism of warfarin in rats (Mu *et al.*, 2006)
G. glabra	Acetaminophen	Increased the excretion of acetaminophen–glucoronide conjugate in rats (Moon and Kim, 1996)
G. glabra	Prednisolone	Decreased CL, increase AUC and Cp of prednisolone (Chen *et al.*, 1991)
GA	Hydrocortisone	Increase effect of hydrocortisone in mice (Teelucksingh *et al.*, 1990)
GA	Oral contraceptive	Hypertension, edema, hypokalemia, increase sensitivity to glycyrrhizin, sensitivity to adverse effects in women is more than in men (Bernardi *et al.*, 1994; De Klerk *et al.*, 1997)

Clearance (CL), area under curve (AUC), plasma concentration (Cp), glycyrrhetinic acid (GA).

adverse effects. Furthermore, consumption of licorice is contraindicated during pregnancy and for patients with liver disorders, hypokalemia like those who are taking cardiac glycosides. The aldosterone effects of licorice root may counteract antihypertensive action of prescribed medications (Cassileth and Barazzuol, 2001). Recently, a direct interaction of glycyrrhetinic acid absorption with sennosides and its derivatives has been studied in humans (Mizuhara *et al.*, 2005). Some drug interactions of licorice which have been reported are summarized in Table 9.

CONCLUSION

In summary, licorice is used throughout the world as a traditional herbal remedy. As for the properties of licorice and its active constituents, it is suggested that their potential roles are evaluated for their effects in the treatment of different kinds of disease such as cancer, atherosclerosis, immunodeficiency, hormone deficiency endocrine and skin diseases. However, it is necessary to carry out further studies to confirm these effects.

Chapter 5
Implications of Acetaldehyde-Derived DNA Adducts for Understanding Alcohol-Related Carcinogenesis

Silvia Balbo and Philip J. Brooks

Abstract Among various potential mechanisms that could explain alcohol carcinogenicity, the metabolism of ethanol to acetaldehyde represents an obvious possible mechanism, at least in some tissues. The fundamental principle of genotoxic carcinogenesis is the formation of mutagenic DNA adducts in proliferating cells. If not repaired, these adducts can result in mutations during DNA replication, which are passed on to cells during mitosis. Consistent with a genotoxic mechanism, acetaldehyde does react with DNA to form a variety of different types of DNA adducts. In this chapter we will focus more specifically on N^2-ethylidene-deoxyguanosine (N^2-ethylidene-dG), the major DNA adduct formed from the reaction of acetaldehyde with DNA and specifically highlight recent data on the measurement of this DNA adduct in the human body after alcohol exposure. Because results are of particular biological relevance for alcohol-related cancer of the upper aerodigestive tract (UADT), we will also discuss the histology and cytology of the UADT, with the goal of placing the adduct data in the relevant cellular context for mechanistic interpretation. Furthermore, we will discuss the sources and concentrations of acetaldehyde and ethanol in different cell types during alcohol consumption in humans. Finally, in the last part of the chapter, we will critically evaluate the concept of carcinogenic levels of acetaldehyde, which has been raised in the literature, and discuss how data from acetaldehyde genotoxicity are and can be utilized in physiologically based models to evaluate exposure risk.

Keywords Acetaldehyde • DNA adducts • N^2-ethyldeoxyguanosine • Upper aerodigestive tract cancers

5.1 Introduction

The designation of alcohol as carcinogenic to humans (Group 1) by the International Agency for Research on Cancer (IARC) represented an important change in our understanding of the health effects of alcohol consumption [1]. While previous IARC working groups had classified the carcinogenicity of alcoholic beverages, they left open the possibility that the carcinogenic effects resulted from contaminants in the alcoholic beverages, rather than alcohol itself. Thus, the important question of the carcinogenicity of alcohol per se was not definitively addressed. The notable aspect of the 2007 working group meeting was that alcohol (ethanol) itself was identified as carcinogenic to humans [2]. This classification therefore allows the scientific community to focus on the mechanistic question of how alcohol in alcoholic beverages increases the risk of cancers at certain sites in the body. Given the diversity of target tissues for alcohol-related carcinogenicity (liver, female breast, colorectum, upper aerodigestive tract), it is possible, and indeed likely, that different mechanisms are involved at different target tissues.

An obvious possible mechanism for the carcinogenicity of alcohol, at least in some tissues, involves the metabolism of ethanol to acetaldehyde. Redressing an oversight from the 2007 monograph, the 2009 IARC working group concluded that "acetaldehyde associated with the consumption of alcoholic beverages is carcinogenic to humans (Group 1)" [3]. This conclusion was based in a large part on the dramatically elevated risk of esophageal cancer from alcohol drinking in individuals who are unable to metabolize acetaldehyde due to a genetic variant in ALDH2 [4–6]. Based on these and other data, the strongest evidence for a causative role for acetaldehyde is for alcohol-related cancers of the UADT. The UADT includes the oral cavity, larynx, pharynx, and esophagus.

It is worth emphasizing here that the IARC Group 1 classification specifically applies to acetaldehyde *associated with the consumption of alcoholic beverages*. Acetaldehyde alone remains classified as Group 2b, possibly carcinogenic to humans. We will return to this topic in the last part of this chapter focusing on carcinogenic levels of acetaldehyde.

Broadly speaking, there are two mechanistically different types of carcinogens: genotoxic and non-genotoxic [7]. Genotoxic carcinogens react directly to chemically modify the DNA, resulting in the increased rate of mutagenesis and therefore increased rate of carcinogenesis. Well-known examples of genotoxic carcinogens are ultraviolet light, components of cigarette smoke, and aflatoxin. In contrast, non-genotoxic carcinogens increase the risk of cancer by mechanisms that do not involve direct DNA damage. Examples of non-genotoxic carcinogenic mechanisms include inflammation, which can result in DNA damage from inflammatory mediators, and hormone-like effects. The two mechanisms are not mutually exclusive. Notably, the IARC carcinogen classifications encompass both genotoxic and non-genotoxic agents. As stated in the preamble to the IARC *Monographs: "*… an agent is termed 'carcinogenic' if it is capable of increasing the incidence of malignant neoplasms, reducing their latency, or increasing their severity or multiplicity." This broad and mechanism-independent aspect of the IARC classification system is intentional;

"The aim of the *Monographs* has been, from their inception, to evaluate evidence of carcinogenicity at any stage in the carcinogenesis process, independently of the underlying mechanisms."

From a mechanistic standpoint, genotoxic and non-genotoxic mechanisms may have different time courses and other significant differences with practical implications for risk assessment and disease prevention (e.g., linear risk extrapolation versus thresholds for exposure; see [7]). Therefore, the main focus of this chapter will be on efforts made and strategies developed to assess the role of direct genotoxicity in the carcinogenic effect of acetaldehyde. Consistent with a genotoxic mechanism, acetaldehyde can react with DNA to form a variety of different types of DNA adducts. Since the general topic of acetaldehyde-DNA adducts was covered in a recent review [8], here we will focus more specifically on the major DNA adduct formed from the reaction of acetaldehyde with DNA, N^2-ethylidene-deoxyguanosine (N^2-ethylidene-dG) and highlight recent data on the measurement of this DNA adduct in the human body after alcohol exposure. Because the results are of particular biological relevance for alcohol-related cancer of the UADT, we will also focus on the histology and cytology of these target tissues, with the goal of placing the adduct data in the relevant cellular context for mechanistic interpretation. We also discuss the sources and concentrations of acetaldehyde and ethanol in different cell types during alcohol consumption in humans. Finally, we will critically evaluate the concept of carcinogenic levels of acetaldehyde, which has been raised in the literature [9–11], and discuss how data from acetaldehyde genotoxicity are utilized to identify exposure risk.

5.2 DNA Adducts from Acetaldehyde and Alcohol

Acetaldehyde's genotoxic effect is attributable to its reactivity. The electrophilic nature of its carbonyl carbon results in reactions with DNA, generating DNA adducts [12]. The main reactions occur with deoxyguanosine (dG) followed by deoxyadenosine (dA) and then deoxycytosine (dC) [6, 13]. The binding of acetaldehyde to these nucleosides leads principally to the formation of a Schiff base on the exocyclic amino groups. The resulting imines are unstable at room temperature and neutral pH. However, these compounds can be stabilized using reducing agents, ultimately resulting in ethyl-adducts which are then easier to detect and to quantify.

The most abundant and well-studied acetaldehyde-DNA adduct is N^2-ethylidene-dG which can be stabilized by reduction to N^2-ethyl-dG. These adducts are illustrated in Fig. 5.1.

The instability of N^2-ethylidene-dG prevents direct investigation of its biological properties. In contrast, N^2-ethyl-dG is stable in aqueous solution, as well as under the conditions used for automated oligonucleotide synthesis. Therefore, most of the experimental data available for the biological effects of N^2-ethylidene-dG are inferred from experiments using N^2-ethyl-dG as a stable analog. This is a common approach in the field of DNA damage and mutagenesis. For example, abasic sites in DNA,

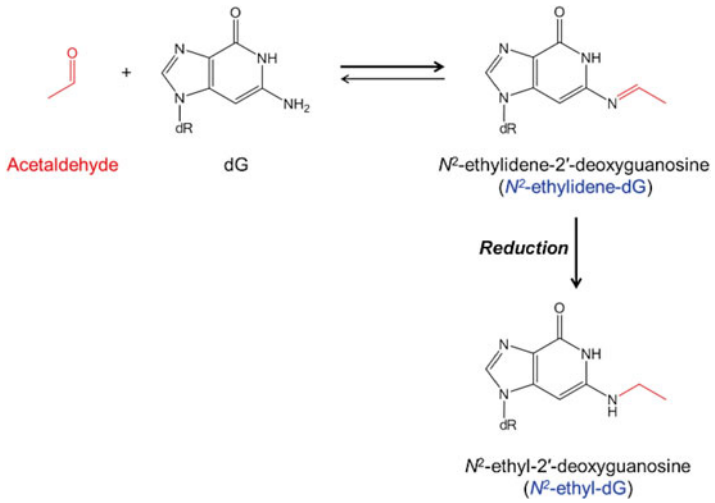

Fig. 5.1 The reaction of acetaldehyde with deoxyguanosine results in the formation of *N2-ethylidendene-dG*; this unstable Schiff base can be converted through a reduction step to the more stable form: N^2-ethyl-dG (dR = 2′-deoxyribose)

which result from depurination, are one of the most common forms of endogenous DNA damage [14]. Because authentic abasic sites are unstable, much of the information we have about their biological effects is derived from studies of tetrahydrofuran as a structural analog [15].

Studies in vitro indicate that N^2-ethyl-dG does not significantly inhibit the replicative DNA polymerase delta [16]. The effects of the lesion on the other major replicative DNA polymerase, epsilon, have not been directly assessed. However, in vivo studies in mammalian cells indicate that the lesion does block replication but is weakly mutagenic, causing primarily −1 frameshift deletion mutations [17–19]. In light of the discussion above, however, it is important to carefully evaluate the limitations of N^2-ethyl-dG as a structural analog.

Figure 5.2 shows energy-minimized models of an N^2-ethylidene-dG paired with dC, an N^2-ethyl-dG paired with dC, and an unmodified dG paired with dC. At first glance, all three models appear similar. The ethyl/ethylidene moiety can be accommodated in the minor groove, with no structural impediment to the guanosine base forming Watson–Crick type H bonds with the appropriate atoms on dC. However, one notable difference is that while dG and N^2-ethyl-dG each form three H bonds with dC, N^2-ethylidene-dG can only form two H bonds. The missing H atom is due to the presence of a double bond between the nitrogen atom and the carbon from acetaldehyde. Viewed from this perspective, the formation of N^2-ethylidene-dG essentially results in G:C base pair with the stability of an A:T base pair.

Studies of frameshift mutagenesis in experimental systems have documented that runs of A:T base pairs are prone to frameshift mutations resulting from a template dislocation mechanism [20]. This observation has generally been explained

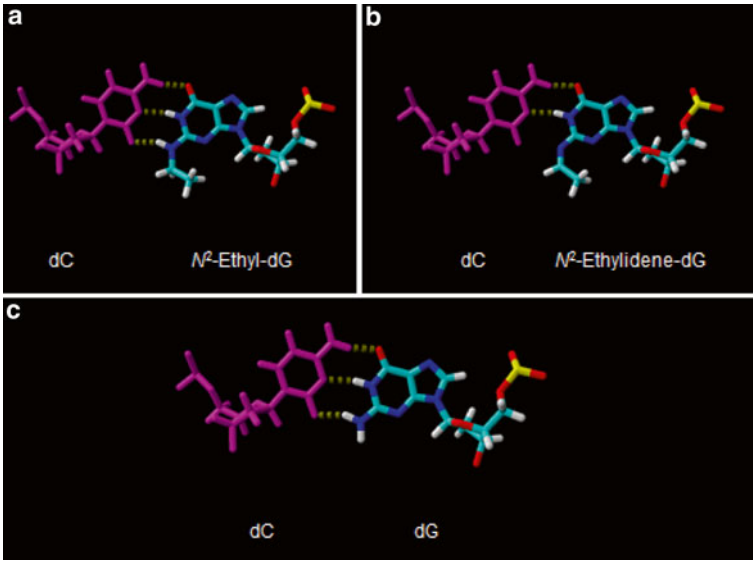

Fig. 5.2 Energy-minimized models showing the difference in base pairing of N^2-ethylidene-dG and N^2-ethyl-dG compared to deoxyguanosine. *Panel A*: the model shows N^2-ethylidene-dG paired with deoxycytosine (dC). *Panel B*: the model shows N^2-ethyl-dG paired with dC. *Panel C*: the model shows an unmodified dG paired with dC

by the reduced stability of A:T base pairs, which increases the probability of primer-template misalignment resulting in frameshift mutations. Adapting this model to N^2-ethylidene-dG in a run of G:C base pairs, an analogous mechanism for frameshift mutagenesis can be hypothesized (see Fig. 5.3). The important point is that it would not be possible to test this hypothesis using N^2-ethyl-dG as a model, because N^2-ethyl-dG forms three H bonds with dC (as shown in panel A of Fig. 5.2). However, this hypothesis could be tested in vivo, perhaps using a yeast strain with run of G:C base pairs in a mutational reporter gene. It should be pointed out, however, that runs of G:C base pairs are generally refractory to frameshift mutagenesis due to their inherent stability.

5.2.1 Other Acetaldehyde-DNA Adducts

In addition to N^2-ethylidene-dG, the most well-studied acetaldehyde-related DNA adducts are the crotonaldehyde-derived propano-dG (CrPdGs) adducts [21]. The condensation of two molecules of acetaldehyde can also produce a reactive electrophile, 3-hydroxybutanal (crotonaldehyde), which can also form a Schiff base on the same amino group of dG. These CrPdG adducts can have multiple biologic effects as a result of their ability to undergo a ring opening reaction. Ring opening yields another aldehyde moiety which can react with proteins to form DNA-protein

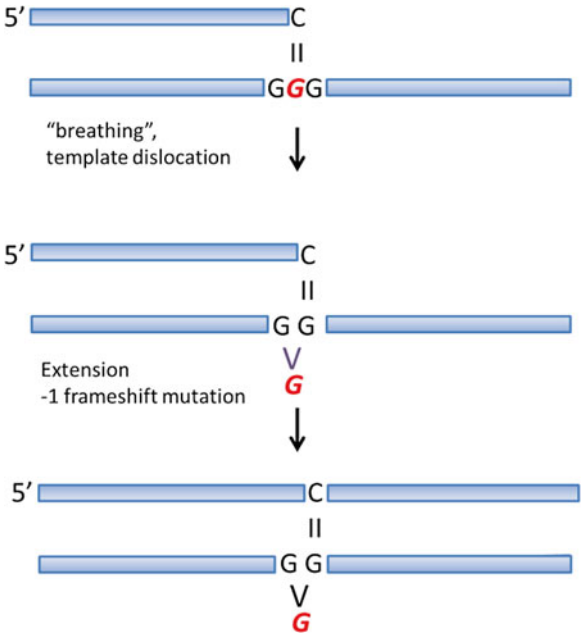

Fig. 5.3 Mechanisms of frameshift mutagenesis hypothesized for N^2-ethylidene-dG

cross-links or (in some sequence contexts) with deoxyguanosine on the opposite strand to form DNA-interstrand cross-links. The biological effects of these adducts have been reviewed recently [8].

It is also worth mentioning the early studies of Fraenkel-Conrat and colleagues, who showed that ethanol and acetaldehyde in combination could react with DNA bases to generate mixed acetal DNA adducts [22]. However, these adducts were very unstable, at least under the in vitro conditions investigated. As such, the biologic significance of these adducts, if any, is currently unclear.

In summary, acetaldehyde has been shown to form several DNA adducts, including N^2-ethylidene-dG and the CrPdG adducts. Under in vivo conditions, which are of the most direct relevance to human carcinogenesis, N^2-ethylidene-dG has been the most well studied, and therefore, we review these studies in the following paragraphs.

5.3 N^2-Ethylidene-dG as a Biomarker of DNA Damage Resulting from Acetaldehyde Derived from Ethanol

As mentioned above, the major reaction of acetaldehyde with DNA occurs on the exocyclic amino group of guanine forming N^2-ethylidene-dG. This adduct is stable in DNA but it easily breaks down when released as a nucleoside.

Fang et al. were the first to report the detection of this adduct, as its reduced form N^2-ethyl-dG, in leukocyte DNA of alcoholics. In their work a ^{32}P-postlabelling method was used for the adduct quantitation. Only samples from heavy drinkers showed detectable amounts of N^2-ethyl-dG likely resulting from the reduction of N^2-ethylidene-dG by endogenous reducing agents such as ascorbic acid and glutathione [23].

In order to avoid the degradation of N^2-ethylidene-dG during DNA hydrolysis and increase the sensitivity of the method, a new approach was developed by Wang et al. [24]. A reducing agent, $NaBH_3CN$, was introduced prior to DNA hydrolysis. Additionally, a stable isotope dilution method was used for the quantitation of the DNA adduct by liquid-chromatography-electrospray ionization-tandem mass spectrometry-selected reaction monitoring (LC-ESI-MS/MS-SRM). The use of this new method allowed a selective detection of N^2-ethyl-dG and an accurate quantitation. By reducing the degradation of the adduct through its conversion into a more stable compound, N^2-ethyl-dG was detected in DNA from all samples analyzed. This resulted in an increased sensitivity which allowed for the detection of lower levels of the DNA adduct, expanding its application beyond the quantitation in samples from heavy drinkers, and set the stage for the broader use of this adduct as a marker for acetaldehyde-induced DNA damage. Since then, N^2-ethyl-dG has been measured in DNA from various samples, for the investigation of the effects on DNA of acetaldehyde from different sources [25, 26].

N^2-Ethyl-dG has been used successfully to measure ethanol-induced DNA damage in HeLa cells expressing ADH1B, which corresponded to the activation of the Fanconi anemia-breast cancer susceptibility (FA-BRCA) DNA damage response network [27]. In a different study, the same DNA adduct was quantified to investigate ethanol-induced DNA damage in the brain of ethanol-treated mice. Higher levels of N^2-ethyl-dG were observed in brain DNA from mice exposed chronically and acutely to ethanol compared to controls [28]. These examples demonstrate that N^2-ethyl-dG is an extremely valuable tool for the investigation of DNA damage associated with acetaldehyde exposure from alcohol consumption and thus for the investigation of alcohol-related mechanisms of carcinogenesis.

The measurement of levels of N^2-ethyl-dG has indeed been crucial in studies focusing on the investigation of effects of alcohol exposure in ALDH2 deficiency. Several studies have used this adduct to detect the DNA damage induced by ethanol exposure in wild-type and *Aldh2* knockout mice, used as a model for *ALDH2* deficiency in humans. Increased levels of the adduct have been found in the liver, esophagus, tongue, and submandibular gland DNA of *Aldh2* knockout mice exposed to ethanol [29, 30]. These findings, together with the results from a study showing increased levels of N^2-ethyl-dG in peripheral blood of ALDH2-deficient alcoholics [31], contributed substantially to the evidence supporting an acetaldehyde-mediated mechanism in alcohol-related carcinogenesis. Together with the epidemiological data showing a dramatic increase of risk for esophageal and head and neck cancers in ALDH2-deficient drinkers, the results from the DNA damage studies contributed to the classification of acetaldehyde related to alcohol consumption as carcinogenic to humans (Group 1) by the IARC [3].

5.3.1 Experimental Studies of Acetaldehyde-DNA Adduct Formation from Alcohol Drinking in Humans

The studies described above clearly demonstrate that increased levels of acetaldehyde-DNA adducts can be observed in animals exposed to ethanol and in human alcohol abusers. However, the studies do not address the minimal amount of ethanol exposure necessary to increase DNA adduct levels or the time course or persistence of the adducts. Moreover, previous studies have not specifically investigated acetaldehyde-DNA adduct formation in humans in a known target tissue for alcohol-related carcinogenesis. Overall, little is known about the formation and lifetime of DNA adducts in the human body. Experimental studies have shown that with constant dosing a steady state concentration of DNA adducts will occur, where the number of new adducts formed equals the number of adducts lost due to repair or instability. However, repair processes vary depending on the cell type and remove different adducts with various efficiencies. Consequently, the lifetime of DNA adducts in vivo can be highly variable according to the tissue or cell type in which they are formed [32]. For instance, easily accessible surrogate tissues such as buccal cells or peripheral blood cells have very different lifetimes. In particular peripheral blood white cells include large cell subpopulations with major differences in lifespan. Lymphocytes are long-lived cells with a life span up to several years, while neutrophils are extremely short-lived cells with a life span of 2–3 days. The quantitation of N^2-ethylidene-dG in these cell types could potentially reflect very different exposure effects and provide very different information on the formation, accumulation, and elimination of the DNA adduct. Therefore, to address these important questions, Balbo et al. performed a biomonitoring study on human subjects before and after consumption of increasing amounts of ethanol [33, 34].

Ten healthy volunteers were recruited. Subjects were required to refrain from any alcohol consumption other than that administered for the study, starting from 1 week prior to the beginning of the experiment and throughout its entire duration. Three increasing alcohol doses were administered during the experiment, one dose a week, starting from the lowest. The alcohol dose administered was selected taking into account gender and weight in order to target specific blood alcohol levels, all below intoxication (defined as a blood alcohol level of 0.08 % [35]). The 3 doses selected for the study can roughly be described as corresponding to 1, 2, and 3 vodka drinks per subject. Overall, the alcohol doses had an ethanol content that ranged between 20 and 50 g which corresponded to an ethanol concentration in the drink ranging between 1.5 and 2.5 M. These concentrations ultimately resulted in a final blood alcohol concentration in the range of 0.01–0.02 M.

Levels of N^2-ethyl-dG were measured in DNA isolated from oral cells collected with a nonalcoholic mouthwash and from white blood cells. Granulocytes and lymphocytes were isolated from the blood to test potential effects of different cellular life span and repair mechanisms. A sample was collected before drinking to establish a baseline and then at several time points after exposure to each dose (2, 4, 6, 24, 48, and 120 h) to assess the kinetics of adduct formation and disappearance.

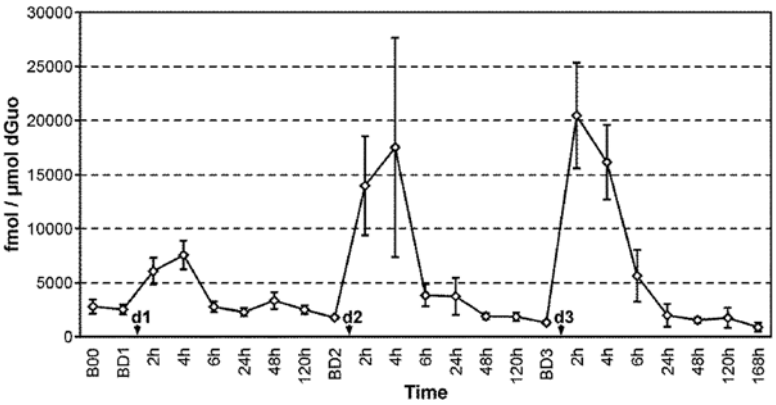

Fig. 5.4 Summary of the results obtained from a study investigating the effects on oral cell DNA of consumption of increasing doses of alcohol. The study was performed on samples collected form ten subjects who abstained from drinking any alcoholic beverage other than the doses provided over the entire duration of the study. The graph reports the mean levels of N^2-ethyl-dG (fmol/µmol dG) measured in oral cell DNA at various intervals before and after three increasing alcohol doses. The first time point reported on the *left* (B00) refers to 1 week before consumption of the first alcohol dose. Starting from this time point, participants began to abstain from consuming any alcoholic beverage. The next time point (BD1) refers to the baseline level detected 1 week later, 1 h before consumption of the first dose (d1, lowest). Subsequently, the graph shows the levels of N^2-ethyl-dG measured at the various time points considered after each dose (2–120 h). The DNA adduct levels were measured at the same time points before and after exposure to the next two doses (d2, intermediate, and d3, highest). Levels of the adduct increased 2 h after exposure even after consumption of the lowest dose and returned to baseline 24 h after exposure. A clear dose–response effect of alcohol on N^2-ethyl-dG levels was found. The baseline time points measured 1 h before the dose (BD1–BD3) are 7 days apart. Values are means and SEs. Data from reference [33, 34]

Considering the results from the oral cavity first, as shown in Fig. 5.4, increased levels of N^2-ethyl-dG were already detected at 2 h after alcohol consumption and reached a peak between 2 and 6 h. Interestingly, adduct levels had returned to baseline after 24 h, indicative of either DNA repair or cell turnover. We will return to this point in the discussion of the histology of the oral epithelia (discussed in detail below). Most importantly, peak adduct levels showed a clear dose–response relationship to the amount of alcohol consumed.

A different pattern of adduct formation was observed in white blood cells after alcohol drinking. Quantitation of the DNA adduct in granulocytes and lymphocytes did not show a major difference between the two cell types. An increase after the alcohol doses was detected, but in contrast to the oral cavity, no clear dose response was observed. Additionally, the high baseline levels and the high intra- and interindividual variability did not allow the clear identification of an effect directly attributable to the alcohol dose.

To our knowledge, this is the first study to investigate the effects of alcohol consumption on the time course of DNA adduct formation in healthy volunteers. All previous published studies on N^2-ethyl-dG levels in humans were done on heavy drinkers or alcoholics [23, 29]. Furthermore, no information on the persistence of

this specific modification was reported. These results clearly demonstrate that even a single drink of alcohol results in a significant and dose-dependent increase in acetaldehyde-DNA adducts in cells in the human oral cavity, a known target tissue for alcohol-related carcinogenesis.

While N^2-ethylidene-dG is the major adduct formed after reaction of acetaldehyde with DNA, as mentioned above, several other adducts can result from acetaldehyde reactions with DNA, although generally they are formed in lower yield. Because of its high levels, N^2-ethylidene-dG is easier to detect and measure and thus could be considered as a general indicator of exposure of DNA to acetaldehyde and a proxy for detection of other DNA modifications. Consequently, these results provide a good starting point for future studies focusing on mapping multiple acetaldehyde-derived DNA modifications and investigating their potential role in the carcinogenic process.

These findings demonstrate the utility of oral cell DNA for the investigation of the role of alcohol-related DNA adducts in head and neck carcinogenesis. These observations support the hypothesis that alcohol drinking increases the risk of oral cancer via a mechanism involving a genotoxic effect of acetaldehyde. Before exploring this question in more detail, however, it is necessary to put the results from Balbo et al. into the relevant cellular context. For this purpose, below we briefly review the anatomy and histology of the oral cavity and esophagus.

5.3.2 Anatomical Considerations

A fundamental aspect of genotoxic carcinogenicity is the formation of mutagenic DNA adducts in proliferating cells. If left unrepaired, these adducts can result in mutations during DNA replication, which are passed on to daughter cells during mitosis. DNA adducts that form in terminally differentiated cells (G0) do not directly contribute to carcinogenesis, because of the absence of DNA replication. As such, it follows that a key issue for interpreting the relationship between DNA adduct formation and carcinogenesis is the cell type in which the DNA adduct formed.

The oral cavity and esophagus are both squamous epithelial tissues, in which cells in the upper layers are continuously replaced by new cells generated in the lower layers (for review see [36]). A schematic representation of these tissues is shown in Fig. 5.5. As indicated in the figure, proliferating cells (i.e., cells that replicate their DNA) are located in the basal and suprabasal layers of the epithelium. After differentiation, cells move up toward the surface of the epithelial layer. During transit, these cells flatten out (desquamate) and are ultimately sloughed off into the saliva or lumen of the esophagus. The time for newly generated cells in the oral cavity to transit from the basal layer through the surface of the (non-cornified) epithelial layer has been estimated at roughly 4 days (in rabbits) [22, 37]. As the DNA labeling index of cells in the basal layers of humans and rabbits is similar, the 4-day transit time is likely to be a reasonable estimate for humans as well.

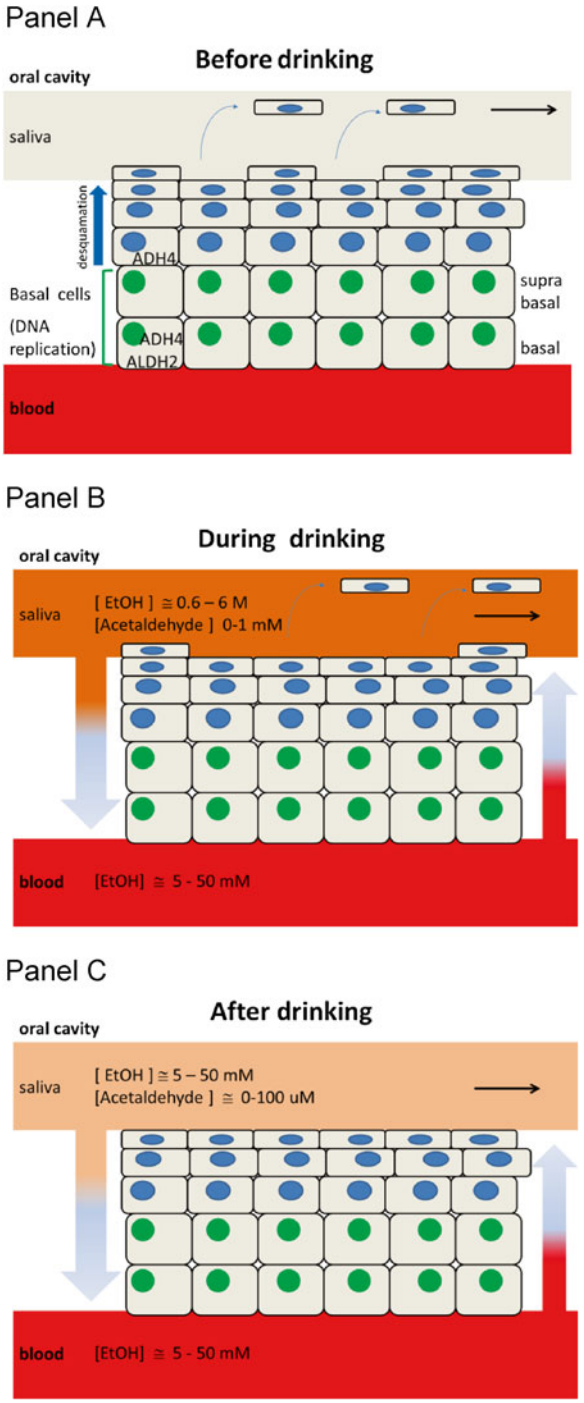

Fig. 5.5 Schematic representation of the squamous epithelial tissue of the oral cavity before, during, and after alcohol drinking. *Panel A* shows the various cell layers: cells in the upper layers are continuously replaced by new cells generated in the lower layers, the basal and suprabasal layers of the epithelium, where proliferating cells (i.e., cells that replicate their DNA) are located. After differentiation, cells move up toward the surface of the epithelial layer. During transit, these cells flatten out (desquamate) and are ultimately sloughed off into the saliva. *Panel B* shows the levels of exposure to alcohol and to acetaldehyde of the various levels of the epithelium when drinking alcohol. In addition to high concentrations of ethanol and acetaldehyde diffusing from the epithelial surface downward into the deeper cell layers (*brown arrow*), some alcohol reaches the blood stream from where it can diffuse into epithelial cells (*red arrow*), allowing metabolism to acetaldehyde in situ. Acetaldehyde levels in the blood are very low and considered negligible for this model. *Panel C* illustrates the levels of exposure to ethanol and acetaldehyde of the various layers of the epithelium after alcohol drinking when the ethanol concentration levels between the saliva and the blood stream reach the equilibrium

When drinking alcohol, the oral cavity and esophagus are transiently exposed to alcohol and acetaldehyde concentrations that are essentially the same as those in the beverage itself. While the time of exposure is only on the order of seconds, the alcohol and acetaldehyde concentrations can be very high. For example, the concentration of ethanol in hard liquor (100 proof) is roughly 7–8 M, in wine approximately 2 M, and in beer between 500 and 700 mM. Acetaldehyde concentrations in alcoholic beverages can vary between undetectable levels (vodka) to roughly 200 mM or more, depending on the beverage [38, 39]. By 30 min after alcohol drinking, salivary ethanol levels have largely equilibrated with blood levels [40, 41].

In addition to the saliva and alcoholic beverage, acetaldehyde is generated within esophageal epithelial cells as a result of ethanol metabolism. Cells of the upper GI tract including the esophagus express ADH7, as opposed to ADH1 proteins that are expressed in the liver. Compared to ADH1, which has a low Km for ethanol oxidation (on the order of 1 mM), the Km of ADH7 is substantially higher (around 25 mM) [42]. However, as noted above, the concentration of ethanol in alcoholic beverages can be in the molar range, which would clearly saturate the enzyme. Moreover, blood alcohol levels during alcohol intoxication could reach 25 mM, or even higher concentrations with heavy drinking, which would result in substantial metabolism to acetaldehyde by ADH7 in epithelial cells. Notably, the catalytic activity of ADH7 (K_{cat}) for acetaldehyde production is 1–2 orders of magnitude higher than ADH1 [42].

Returning to the study of Balbo et al., the use of a mouthwash to obtain cells for analysis would primarily collect those terminally differentiated epithelial cells that were at the surface of the epithelial cell layer, in contact with the contents of the oral cavity, including those cells in the process of sloughing off (see Fig. 5.5 panel A). Therefore, acetaldehyde-DNA adduct levels in these cells does not directly monitor adduct levels in the proliferating cell layers that are of greatest relevance to carcinogenesis.

An important aspect of the Balbo et al. findings is the reduction in adduct levels over time, reaching baseline by 24 h after alcohol drinking. Since the half-life of N^2-ethylidene-dG in DNA at 37 °C is 24 h, the return of adduct levels cannot be completely explained by spontaneous adduct loss. If so, there are at least two possible explanations for the return of adduct levels to baseline. One possibility is that the adducts were repaired via DNA repair. While neither base excision repair nor direct repair have been shown to be able to remove N^2-ethyl-dG (used as a surrogate for N^2-ethylidene-dG), it is possible that the nucleotide excision repair mechanism could remove the lesion. Another possibility is that the decline in adduct levels over time reflects changes in the cell population being sampled. As shown in Fig. 5.5, the epithelium is not a static cell population, but one in which cells are born, differentiate, and depart over time, in a directional manner. As such, the cells collected at the 24 h time point would have been in a different physical location relative to the epithelial surface during the alcohol drinking and immediately afterwards, when salivary acetaldehyde levels would be highest. Therefore, to the extent that N^2-ethylidene-dG adducts were the result of salivary acetaldehyde formation, the cells collected at the 24 h time point may have been at least partially protected from DNA damage by the overlying cells.

The two possibilities are not mutually exclusive, and both could be assessed experimentally. The role of NER could be readily tested by exposing normal and NER-deficient human cells to acetaldehyde, then assaying the disappearance of N^2-ethylidene-dG adducts over time in the two cell types. Assessing the kinetics of adduct formation in different cell layers of the oral epithelium in vivo is more technically challenging. Theoretically, antibodies against acetaldehyde-DNA adducts could be developed, which might be useful for a semiquantitative assay of adduct levels in different cell types with human biopsies. However, the sensitivity and specificity of such antibodies are difficult to ensure. Alternatively, the proliferating cell layer could be dissected out for adduct analysis (e.g., by laser capture microdissection), but the amount of DNA would be insufficient for analysis by mass spectrometry given the sensitivity of the technique currently. Conceivably, cell types of interest could be separated in bulk using cell-sorting techniques (e.g., [43]). However, this would require amounts of tissue that could not be obtained from humans.

Regarding animal models, it is important to note here that there is a major species difference in the K_m of ethanol oxidation by ADH7 between humans, mice, and rats. Specifically, while as noted above the Km of the human ADH7 for ethanol is approximately 25 mM [42], that of the mouse ADH7 homolog is roughly 200 mM [44], and for the rat is >2 M [45]. Therefore, to the extent that ethanol metabolism in oral or esophageal epithelial cells plays an important role in alcohol-related acetaldehyde-DNA adduct formation, the major difference in ADH7 for ethanol metabolism is a significant limitation of either rodent species as an animal model of humans.

5.4 Why Are ALDH2-Deficient Individuals at Such Elevated Risk of Esophageal Cancer from Drinking Alcohol?

The dramatically elevated risk of esophageal cancer in individuals with deficient ALDH2 is well known [46, 47]. However, the question of why these individuals are at such elevated risk of esophageal cancer, as opposed to other types of cancers, is not well understood. It has been shown that ALDH2-deficient individuals experience higher levels of salivary acetaldehyde from ethanol [48, 49] Importantly, this difference is only detectable when ethanol is actually ingested [50]. However, it is not clear that the difference in acetaldehyde concentrations in the saliva during alcohol drinking can fully explain the dramatically elevated esophageal cancer risk. In this context, a crucially important question concerns the localization of the ALDH2 enzyme in cells of the esophageal epithelium. Yin et al. [51] reported that ALDH2 activity in homogenates of the human esophageal mucosa, as measured on agarose gels, was barely detectable. Using standard enzymes assays, "low K_m ALDH" (assayed at 200 μM acetaldehyde) was reported to be less than 10 % of the high K_m form. However, these studies did not completely exclude the possibility of ALDH2 expression in a population of cells in the esophagus.

In contrast to biochemical studies, immunohistochemical studies of ALDH2 in the human esophagus [50, 52] did in fact detect ALDH2 staining in a subset of cells,

specifically cells localized to the basal cell layer where proliferating cells are found. The ALDH2 antibody used in this work was developed by Weiner and colleagues [53] and had been validated using tissues from knockout mice lacking Aldh2. In support of these findings, data available on a public database shows that ALDH2 mRNA can be detected in the human esophagus (http://www.ncbi.nlm.nih.gov/geoprofiles/83899354) [54]. Interestingly, the staining intensity varied depending upon the drinking history of the tissue donors: the strongest staining was more often observed in samples from individuals with a history of alcohol drinking. These observations raise the intriguing possibility that ALDH2 expression may be inducible by heavy alcohol drinking in the human esophagus. Consistent with these observations and the idea that ALDH2 can be inducible, ALDH2 expression can be increased by low pH in a human esophageal cell line (http://www.ncbi.nlm.nih.gov/geoprofiles/11619953) [55].

Taken together, these data indicate that ALDH2 is expressed in proliferating cells of the human esophagus, where it could play a role in protecting genomic DNA against acetaldehyde generated from ethanol metabolism by ADH7 in situ. If so, then the absence of this activity in proliferating esophageal cells of ALDH2-deficient alcoholics would provide a compelling explanation for the dramatically elevated risk of esophageal cancer from high levels of alcohol drinking in this population.

One final point to be made here is that the proliferating cell layer of the oral and esophageal epithelium is not static. Under normal conditions, cell proliferation and differentiation are balanced to maintain the structure and function of the epithelium. However, in response to wounding or damage, the balance between proliferation and differentiation can shift to regenerate the damaged tissue [56]. An important study by Salaspuro and colleagues [57] in fact demonstrated that chronic exposure of rats to acetaldehyde in the drinking water does increase the size of the proliferating cell compartment in oral and gastrointestinal epithelia, as measured by the thickness of the epithelial layer and number and depth of cells staining for the proliferation maker Ki67. While the concentration of acetaldehyde in the drinking water used in that work (120 mM) is far in excess of what would be considered clinically relevant during alcohol drinking in humans, as noted by the authors, acetaldehyde is highly volatile (boiling point 24 °C) and would therefore likely diffuse from the bottles, reducing the actual concentration. Also, the bottles were only changed every three days. Therefore, the actual acetaldehyde concentration that tissues were exposed to from the drinking water was likely to be far less than 120 mM, especially by the third day after bottle change. Also, as shown in Fig. 5.5b, during alcohol drinking in humans, acetaldehyde can be generated intracellularly from ethanol metabolism at high blood ethanol concentrations, and these intracellular levels could be quite high, especially in ALDH2-deficient individuals. This issue could be addressed in the laboratory using cells expressing human ADH7, exposed to different ethanol concentrations spanning the range that could be generated in the blood during heavy alcohol drinking in humans.

The expansion of the proliferative cell compartment and hyperregeneration as a result of the toxic or damaging effects of acetaldehyde derived from ethanol metabolism (see [58, 59]) would be examples of non-genotoxic mechanisms for

acetaldehyde-related carcinogenesis. However, these mechanisms could synergize with genotoxicity, in that more proliferating cells with mutagenic DNA adducts essentially expand the target tissue for carcinogenesis. It is therefore likely that acetaldehyde acts as both a genotoxic and non-genotoxic carcinogens in the human UADT.

5.5 Is There a "Carcinogenic" Level of Acetaldehyde?

As noted in the Introduction, the 2009 IARC classification specifically identifies acetaldehyde associated with the consumption of alcoholic beverages as a Group 1 carcinogen. Acetaldehyde alone remains classified in Group 2B (possibly carcinogenic to humans). However, the concept of a "carcinogenic level of acetaldehyde" (variously described as between 50 and 100 μM) has entered the literature [11, 39, 60]. As this term is based upon studies of DNA adduct formation, and genotoxic end points, we would like to briefly discuss its derivation and implications.

One of the studies cited in support of this concept was the work of Theruvathu et al. [61] (one of us, P.J.B., was an author on that paper). This work was intended to address a specific mechanistic question, which was whether polyamines could stimulate the formation of CrPdG adducts in DNA during exposure to acetaldehyde. In that study, Theruvathu et al. incubated purified genomic DNA with increasing concentrations of acetaldehyde, with or without a physiologically relevant concentration of polyamine, at 37 °C for 24 h [61]. While the acetaldehyde concentrations used were within the range that could plausibly occur in the human body during alcohol drinking, the work was not intended to be a basis for establishing a mutagenic or carcinogenic level of acetaldehyde. DNA adduct formation in living cells exposed to acetaldehyde is likely to be much lower than when pure DNA is exposed, due to reactions of acetaldehyde with other cellular molecules, as well as ongoing DNA repair. In fact, it would be important and relevant to assess CrPdG adduct levels in human cells exposed to different acetaldehyde concentrations for different periods of time. Highly sensitive and specific assays for CrPdG adducts in cellular DNA have been developed and could be used utilized for this purpose [31].

Another study that has been cited to support the carcinogenic level of acetaldehyde is the work of Obe and Ristow [62], who investigated the effect of acetaldehyde on sister chromatid exchanges (SCE) in mammalian cells. The lowest concentration that was shown to increase SCE levels in that study was roughly 90 μM. While an increase in SCEs is evidence of genotoxicity, SCEs are not mutations, and their relevance for predicting cancer risk is controversial [63].

A more important issue that is not explicitly considered when discussing carcinogenic levels of acetaldehyde is the histology of the oral cavity. As we have illustrated in Fig. 5.5, the proliferating cells in the oral cavity that are of most relevance to oral cancer lie several layers below the epithelial surface. For this reason, the concentration of acetaldehyde that proliferating cells in the oral epithelium are actually exposed to will be much lower than the levels in saliva, due to the reaction of acetaldehyde with components of the overlying, terminally differentiated cells.

Estimating a carcinogenic acetaldehyde concentration in the oral cavity based upon an acetaldehyde concentration that increases SCEs in monolayer cells in tissue culture fails to take this protective cell layer effect into account.

It is in fact possible to develop valid models of the effect of acetaldehyde on different epithelial tissues, which could be relevant to understand carcinogenic mechanisms, and to provide a basis for risk assessment. Templates for such an approach are physiologically based pharmacokinetic models for vinyl acetate toxicity and carcinogenesis in the oral and nasal epithelium [63]. Importantly, vinyl acetate is metabolized to acetaldehyde and acetic acid in epithelial cells, and therefore, some of the information that was used in developing the vinyl acetate models may be directly applicable to acetaldehyde carcinogenicity as well. As in the case of vinyl acetate, different models should be developed for different tissues, taking into account the expected concentrations of ethanol and acetaldehyde, as well as the time course of exposure, and considering the unique biology of different tissues (e.g., oral cavity versus esophagus versus colorectum).

5.6 Summary and Conclusions

The ability of acetaldehyde to form covalent adducts with DNA is consistent with a genotoxic mechanism for alcohol-related carcinogenicity, but does not prove such a mechanism, nor does it rule out non-genotoxic effects. More data on the kinetics of acetaldehyde-DNA adduct formation and repair in specific cell types in target tissues for alcohol-related carcinogenicity will be important to fully understand carcinogenic mechanisms. Data from humans is of the most direct relevance to human carcinogenesis, and whole genome sequencing of human tumors may provide evidence of genetic signatures corresponding to specific DNA adducts (see [8]). However, given the ethical and practical limitations of collecting relevant tissues from human, data from well-designed animal studies, taking into account relevant species differences as noted above, will also provide important mechanistic insights of relevance not only for alcohol-related carcinogenesis but also to the broader question of risk assessment for acetaldehyde alone.

ADVANCES IN HEPATOLOGY

Current Developments in the Treatment of Hepatitis and Hepatobiliary Disease

Section Editor: Eugene R. Schiff, MD

Alcoholic Liver Disease

Lauren A. Beste, MD, MSc
Clinical Assistant Professor
Department of Medicine
University of Washington School of Medicine
VA Puget Sound Health Care System
Seattle, Washington

G&H What is alcoholic liver disease, and how prevalent is it in the United States?

LB Alcohol abuse is the third leading preventable cause of death in the United States, according to the Centers for Disease Control and Prevention. Alcoholic liver disease is one of many conditions associated with alcohol misuse. It has a broad spectrum, ranging from mild fatty changes in the liver to frank cirrhosis of the liver. Nearly all individuals who consume a significant amount of alcohol (ie, >40 grams a day) will develop early fatty changes that can be seen on liver biopsy, and approximately 10% to 20% will eventually go on to develop cirrhosis.

In addition, there is another distinct form of alcoholic liver disease, acute alcoholic hepatitis, which is a lethal and feared complication of alcohol abuse. This condition occurs in approximately 30% to 45% of alcoholics at some point in their lives. This is a dangerous disease in which the 28-day mortality in severe cases can be as high as 50%.

G&H Have there been any recent trends in the epidemiology of alcoholic liver disease?

LB In the United States, the prevalence of alcoholic liver disease is essentially flat, with perhaps a very slow downward trend in the past 5 years or so. In the general population, alcohol has been observed to play a role approximately half of the time in hospital discharges related to cirrhosis, so it is estimated that approximately 50% of cirrhosis cases are alcohol-related.

I work in the Veterans Affairs (VA) health care system, where the incidence, or rate of new cases, of alcohol-related liver disease has been starting to trend downward since approximately 2010, and the overall prevalence (ie, the total number of cases per 100,000 in the general population) has essentially been stable. In the VA health care system, alcohol accounts for approximately 30% of cirrhosis cases, and there is another 30% of patients who have both alcoholic liver disease and another liver disease, such as viral hepatitis. Therefore, in the VA health care system, alcohol is a factor in approximately 60% of all cases of cirrhosis. Other data suggest that this is similar in the general US population as well.

G&H What other consequences and complications are associated with alcoholic liver disease?

LB Alcohol abuse is very costly and causes significant morbidity and mortality. All of the health consequences of alcohol, not just those limited to the liver, were estimated to account for 11% of the total US health care cost in 2006. The annual inpatient cost for alcohol-related cirrhosis, not including outpatient treatment, was approximately $850 million in 2014, according to the National Institute on Alcohol Abuse and Alcoholism. Up to 50% of severe cases of acute alcoholic hepatitis will lead to death, even with medical support.

G&H Are there any ways to counteract these consequences of alcoholic liver disease?

LB Of course, the best way to counteract alcoholic liver disease is prevention. Unfortunately, for US patients who already engage in problematic alcohol use, treatments are

very often limited in terms of access and efficacy. Once cirrhosis or acute alcoholic hepatitis develops, quitting drinking becomes a matter of life and death.

G&H Could you expand on the risk of mortality in these patients?

LB Alcoholic liver disease is the second most common cause of disease in patients who are listed for liver transplant, but listed patients represent a highly selected group, given that patients with active substance use disorders are generally ineligible for transplant listing. In terms of mortality rates, an estimated 18,000 people in the United States died of alcoholic liver disease in 2013, and the death rate is highest in younger and middle-aged individuals. However, these numbers are likely underestimates because alcohol is a cofactor in other liver diseases and therefore may not be accurately counted as a cause of death. For example, in people who have viral hepatitis and alcoholic liver disease, alcohol is often not listed as one of the main causes of death.

G&H Should patients with alcoholic liver disease be screened for other conditions?

LB The American Association for the Study of Liver Diseases recommends that all patients with cirrhosis, including those with alcoholic cirrhosis, be screened regularly for hepatocellular carcinoma. Patients with alcoholic cirrhosis should also receive routine screening for gastroesophageal varices.

In addition, all individuals who are known or suspected to misuse alcohol should undergo additional screening for mental health and psychosocial concerns. This would include asking about comorbid conditions such as nonalcohol substance use, mental illness, and housing insecurity. Management of these comorbidities is very complex and requires multidisciplinary support from other services, such as primary care, mental health, and social work.

G&H What symptoms are associated with this condition? Are any patients asymptomatic?

LB Presentations of patients with alcoholic liver disease can vary. Alcoholic liver disease is frequently asymptomatic in its early stages, which is why health care providers should be vigilant and should screen patients for alcohol use as part of routine practice.

Patients with acute alcoholic hepatitis are often extremely ill, and the condition can manifest as liver failure. Clinically, the classic presentation for acute alcoholic hepatitis is a patient with a history of alcohol abuse who presents with a fever, enlarged liver, and jaundice. Often, the patient also has leukocytosis and moderately elevated transaminase levels.

Finally, there is a subset of patients who have alcohol-related cirrhosis. These patients can be asymptomatic in the early stages, but when they develop decompensated liver disease, they become highly symptomatic.

G&H How is alcoholic liver disease usually diagnosed?

LB Usually, alcoholic liver disease can be diagnosed based on patient history and laboratory test results, especially if the patient has examination findings that suggest chronic liver disease. Sometimes, a liver biopsy is performed if the diagnosis is not clear or if there are multiple disease etiologies suspected. Liver biopsy is still the gold standard for diagnosis. However, because liver biopsy is so invasive and carries a risk of complications, clinical practice is moving toward noninvasive methods of ascertaining liver fibrosis in lieu of liver biopsy.

G&H Other than alcohol abuse, are there any risk factors for alcoholic liver disease?

LB With research on this issue starting to enter the literature, we are developing a better understanding of all of the risk factors for alcoholic liver disease beyond just the amount and duration of alcohol intake. For example, alcoholic liver disease appears to be more likely to occur in women, younger people, and those with poor nutritional status. There are also multiple genetic factors that we are only starting to understand related to how the body breaks down ethanol and how it handles inflammation.

There is an emerging new body of research on the relationship between the gut microbiome, the liver, and alcoholic liver disease. It turns out, interestingly, that alcohol disrupts the mucosal barrier of the gut, which leads inflammatory bacterial products called lipopolysaccharides to enter the blood supply. This causes liver inflammation to accelerate and, if the process spirals out of control, it produces the clinical syndrome of alcoholic hepatitis.

G&H How are these patients treated? Is cessation of alcoholic intake sufficient?

LB Once someone develops acute alcoholic hepatitis, a number of interventions have traditionally been used. An exciting recent trial on this subject was STOPAH (Steroids or Pentoxifylline for Alcoholic Hepatitis), which was a randomized trial of 2 commonly used drugs for alcoholic hepatitis, pentoxifylline and prednisolone. The trial found that neither of these drugs has a sustained benefit

on mortality after 28 days, and only prednisolone reduces mortality before 28 days. Thus, the researchers concluded that pentoxifylline should no longer be used for treatment of acute alcoholic hepatitis.

My personal opinion is that after 28 days, survival really depends on the patient quitting drinking. There is no drug that will beat alcohol abstinence in terms of the long-term impact on patient prognosis. Even so, approximately one-third of patients with alcoholic cirrhosis who quit drinking will be dead in 5 years. Thus, even with alcohol cessation, there is still a significant risk of mortality.

Dr Beste has no relevant conflicts of interest to disclose.

Abstract

This study was designed to determine the genotoxic effects of visible (400–800 nm) and ultraviolet A (UVA)/visible (315–800 nm) lights on human keratinocytes and CHO cells. The alkaline comet assay was used to quantify DNA-damage. In addition, photo-dependent cytogenetic lesions were assessed in CHO cells by the micronucleus test. Three protective compounds [ectoin, L-ergothioneine (ERT) and mannitol] were tested with the comet assay for their effectiveness to reduce DNA single-strand breaks (SSB). Finally, the genomic photoprotections of two broad-band sunscreens and their tinted analogues were assessed by the comet assay. The WST-1 cytotoxicity assay revealed a decrease of the keratinocyte viability of 30% and 13% for the highest UVA/visible and visible irradiations (15 and 13.8 J/cm^2, respectively). Visible as well as UVA/visible lights induced DNA SSB and micronuclei, in a dose-dependent manner. The level of DNA breakage induced by visible light was 50% of the one generated by UVA/visible irradiation. However, UVA radiations were 10 times more effective than visible radiations to produce SSB. The DNA lesions induced by visible and UVA/visible lights were reduced after a 1-h preincubation period with the three tested compounds. The maximal protective effects were 92.7%, 97.9% and 52.0% for ectoin (0.1 mM), ERT (0.5 mM) and mannitol (1.5 mM), respectively, against visible light and 68.9%, 59.8% and 62.7% for ectoin (0.1 mM), ERT (0.5 mM) and mannitol (1.5 mM), respectively, against UVA/visible light. Thus, visible light was genotoxic on human keratinocytes and CHO cells through oxidative stress mechanisms similar to the ones induced by UVA radiations. The four tested sunscreens efficiently prevented DNA lesions that were induced by both visible and UVA/visible irradiations. The tinted sunscreens were slightly more effective that their colorless analogues. There is a need to complement sunscreen formulations with additional molecules to obtain a complete internal and external photoprotection against both UVA and visible lights.

Keywords: Visible light; Comet assay; Oxidative damage; In vitro micronucleus; Protective compounds; Sunscreens

1. Introduction

Over the years, changes in lifestyle have led to a significant increase in the human exposition to solar radiations, leading to a dramatic rise in the incidence of skin cancers [1]. Photo-induced cancers are due to a complex multistage phenomenon, mediated via alterations in various cellular mechanisms [2]. Cell initiation is usually considered as the first step in photo-carcinogenesis processes. It essentially consists in irreversible genetic alterations, which ultimately lead to DNA mutations [2]. Ultraviolet (UV) radiations are known to induce DNA lesions, and the implication of ultraviolet A radiations (UVA, 315–400 nm) in these genotoxic damages has been recently proven, although their accurate biological effects are still unclear [3]. UVA radiations represent 95% of natural ultraviolet reaching the Earth's surface. These radiations are

less energetic than ultraviolet B (UVB, 280–315 nm) but, because of longer wavelengths, can pass through standard glass like window and automotive glasses [4]. They penetrate deeply into the basal layer of the human skin, and may affect highly proliferative cells like keratinocytes and melanocytes [5]. At a molecular level, the biological effects of UVB and UVA are different: UVB are responsible of direct photolesions on DNA, i.e. cyclobutane pyrimidine dimers (CPDs) and 6-4 photoproducts [6,7], leading, when they are not repaired, to mutagenesis [8]. In contrast, UVA radiations are only weakly absorbed by DNA, thus UVA genotoxicity is mainly mediated by indirect mechanisms: UVA can interact with endogenous chromophores like porphyrins, bilirubin, flavins, melanin and melanin precursors [9] which act as photosensitizers. These molecules may ultimately generate reactive oxygen species (ROS). Moreover, high UVA doses (50–200 J/cm^2), have been shown to generate CPDs, through a triplet photosensitization mechanism that involves unidentified chromophore(s) [10–12]. Cells possess natural antioxidant defense mechanisms to counteract oxidative aggressions but, when these systems become overwhelmed, the reactive species can cause cell injuries and particularly direct damage to DNA [9]. The genotoxic effects of ROS include oxidized bases like 8-oxo-7,8-dihydro-2′-deoxyguanosine (8-oxodG) [13] and DNA single-strand breaks (SSB) [14]. A long-term exposure to UVA could lead to photoageing, photodermatoses [15,16], immunosuppression [17], and photo-carcinogenesis [18].

Visible light (400–800 nm) has been used for a long time for its therapeutic effects particularly in dermatological diseases [19] and in some localized cancers [20]. However, the photogenotoxic outcomes of visible radiations on cellular DNA are probably underestimated, since UVA and visible radiations are often studied together [21,22]. Some studies have already revealed the genotoxic effects of blue light often used in therapeutic: blue light has been shown to induce DNA SSB, sister chromatid exchanges [23] and intracellular ROS [24]. Visible light could therefore exert an indirect genotoxic effect via oxidative DNA lesions [25].

Chemical protection against photodamage includes (i) the use of protective compounds (internal photoprotection), such as ectoin, L-ergothioneine (ERT) [26] or mannitol [27] to reinforce the antioxidant potential of the cells (ii) the application of broad-spectrum sunscreens (external photoprotection) [28] to reduce the amount of UV radiations reaching the skin. Efficacy of these two approaches can be assessed by using the single cell gel electrophoresis assay, also called the comet assay, which is a simple, reliable and sensitive technique for the evaluation of DNA strand breaks and alkali-labile sites in individual eukaryotic cells [29]. It has been efficiently used to quantify DNA-damage induced by ultraviolet radiations, to assess the genomic photoprotection of sunscreens against UVA radiations [30,31] and to evaluate the photoprotective effectiveness of various antioxidants [32]. Photo-dependent cytogenetic lesions may be evaluated by the micronucleus (MN) test [33,34]. This assay is considered as a sensitive tool to evaluate chromosomal damage induced by chemical or physical agents, leading to clastogenic (breaking) or aneugenic (abnormal segregation) events [35].

In this study, we first evaluated the genotoxic effects of visible light (400–800 nm) by the alkaline comet assay on human normal keratinocytes, and the in vitro micronucleus test on Chinese Hamster Ovary (CHO) cells. Then, the photoprotective capacities of three exogenous compounds (ectoin, ERT and mannitol) and four broad-spectrum sunscreens against UVA/visible and visible irradiations were measured by the comet assay.

2. Materials and methods

2.1. Reagents

Most of the chemicals used for cell cultures, comet assay and micronucleus test were provided by Sigma–Aldrich (Saint Quentin Fallavier, France). Fetal calf serum, Ca^{2+} and Mg^{2+} free phosphate-buffered saline (PBS), trypsin–ethylenediamine-tetra-acetic acid (trypsin/EDTA, 0.05%: 0.02%, v/v) and trypsin 2.5% (in physiological serum, v/v) were from Eurobio (Les Ulis, France). Agarose for the comet assay was from Promega (Charbonnières, France). Bovine pituitary extract (BPE), recombinant epidermal growth factor (rEGF), keratinocyte serum-free medium (K-SFM) and PBS with Ca^{2+} and Mg^{2+} were purchased from GIBCO-BRL (Cergy Pontoise, France).

Sunscreen formulations Photoderm SPF 50+® (tinted and not tinted) and Photoderm Max SPF100® (tinted and not tinted) were graciously supplied by Bioderma laboratories (Lyon, France).

2.2. Irradiation procedure

Irradiation experiments were carried out with a Suntest CPS+ solar simulator (Atlas Material Testing Technology BV, Moussy le Neuf, France) equipped with a xenon arc lamp (1100 W) and special glass filters restricting transmission of light below 290 nm and near IR-blocking filter. The irradiation intensity was fixed at 500 W/m^2 for the comet assay or 750 W/m^2 for the micronucleus assay. The temperature of the samples was kept at 4 °C using a 10% polypropylene glycol in distilled water cooling system into the irradiation chamber. UVA–visible light (315–800 nm) was obtained using the solar ID65 filter plus a window glass filter and visible light alone (400–800 nm) was obtained with a yellow GG 420 nm cut off filter (Schott AG, Clichy, France), placed inside the irradiation chamber and maintained at 3.5 cm above the slides by an appropriate support. The total irradiation dose corresponded to 8% UVA and 92% visible light. The spectral irradiance of the xenon lamp equipped with UVA and visible cut-off filters is reported in Fig. 1.

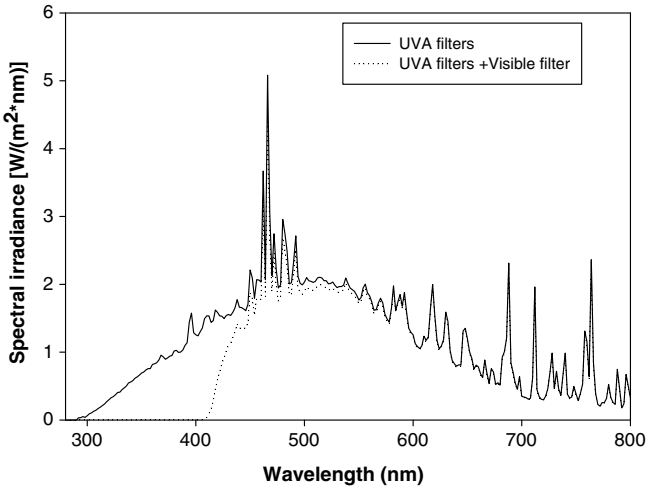

Fig. 1. Irradiation spectra of the xenon arc lamp equipped with UVA and UVA/visible filters used with the Atlas Suntest CPS+. Solid line: Irradiation spectrum of the xenon lamp equipped with the UVA/visible filter (315–800 nm). Dotted line: Irradiation spectrum of the xenon lamp equipped with the visible filter (400–800 nm).

2.3. Cell cultures

Cultures of human primary skin keratinocytes were carried out from neonatal foreskins, and isolation of keratinocytes was conducted as already described [26]. Briefly, after cutting up of the foreskin in small (5 × 5 mm) fragments, skin was incubated in 2.5% trypsin (v/v in physiological serum) during 90 min at 37 °C with gentle shaking. Trypsin was inactivated with 50 μl of fetal calf serum, dermis was eliminated and epidermis fragments were transferred into PBS. The cell pellet was resuspended by pipetting and cells were centrifuged at 1200*g* for 5 min. Finally, cells were seeded in 25 cm^2 flasks containing 7 ml complete K-SFM (with BPE 25 μg/ml and rEGF 0.1–0.2 ng/ml). Cultures were maintained at 37 °C and 5% CO_2/95% air in a humidified incubator. The culture medium was changed every 2 days and pure keratinocytes cultures were generally obtained after 2 weeks.

Chinese Hamster Ovary cells (CHO-K1, ATCC), were selected for their suitability for the MN assay [36]. They were cultured in McCoy's 5A culture medium supplemented with 10% fetal calf serum, penicillin (100 units/ml), streptomycin (10 μg/ml) and 1 mM glutamine. Cultures were kept in humidified incubator at 37 °C with 5% CO_2 and sub-cultured every 2 days.

2.4. Cytotoxicity test

Keratinocyte viability was assessed after exposure to each dose of UVA and/or visible radiation implemented in the comet assay by a cell proliferation assay using WST-1 reagent. WST-1 is a tetrazolium dye that is cleaved by mitochondrial dehydrogenases in living cells to a formazan dye with an absorbance at 450 nm. Briefly, keratinocytes were plated 24 h before experiment on a 96-well multiplate, and then submitted to irradiation with UVA/visible or visible light in PBS with calcium and magnesium. After irradiation, cells were washed and WST-1 in culture medium was added to each well. Following a 30-min incubation period at 37 °C, absorbance at 450 nm was measured by a MRX® II microplate reader (Dynex Technologies, VA, USA).

2.5. Quantification by the comet assay of DNA-damage induced by UVA/visible and visible radiations on human normal keratinocytes

2.5.1. Slide preparation and irradiation procedure

The day before the experiment, keratinocytes (10^5 cells per condition) were plated in 60-mm Petri dishes and kept at 37 °C in a humidified atmosphere containing 5% CO_2. For each irradiation dose, an internal standard was incorporated: 10^5 cells were incubated separately with 60 μM of methyl-methane-sulfonate (MMS) at 37 °C for 2 h before slide preparation.

The alkaline version of the comet assay was carried out according to the procedure of Singh et al. [37] with minor modifications as described previously [38]. Two slides were prepared per condition. Twenty-four hours before the experiment, the slides were covered with 1.8% normal melting-point agarose (NMPA) prepared in Ca^{2+} and Mg^{2+} free PBS and were dried for 12 h. The day of the experiment, 85 μl of normal agarose (0.8%, w/v in PBS) were layered on to the slides, and a coverslip was applied. After solidification of the agarose on an ice bath, the coverslip was removed. The following steps were performed under yellow light to avoid additional DNA lesions. After trypsinization of the keratinocytes, the cells were resuspended at a density of 10^5 cells ml^{-1} and were centrifuged at 3000*g* for 5 min. The cell pellet was diluted into 75 μl of 0.5% molten low melting-point agarose (LMPA) and this suspension was added as a second layer on the slides. A coverslip was immediately applied over the agarose, and slides were maintained on ice for hardening of the agarose. Then, coverslips were removed, and a final layer of 75 μl of 0.5% LMPA was added. After coverslipping the slides, agarose was allowed to harden on ice. Finally, coverslips were removed and the slides were irradiated at 5, 10 or 15 J/cm^2, with UVA/visible with or without the visible light filter. Negative control and internal standard slides were maintained in the dark.

2.5.2. Comet assay

After the irradiation procedure, the slides were immediately placed in freshly prepared lysis solution (2.5 M NaCl, 100 mM Na_2 EDTA, 10 mM Tris, pH 10, 1% L-lauroyl sarcosinate, and 10% dimethylsulfoxide and 1% Triton X-100) for 90 min at 4 °C to remove cellular proteins. Then the slides were transferred in a horizontal electrophoresis unit and the DNA unwinding was carried out in a fresh electrophoresis buffer (300 mM NaOH, 1 mM Na_2EDTA [pH > 13]) for 20 min at room temperature. Electrophore-

sis was next conducted in the same buffer during 20 min (25 V, 300 mA). Finally, the slides were covered three times during 5 min with 0.4 M Tris buffer (pH 7.5) and dehydrated in 100% methanol. After drying, slides were maintained in dry atmosphere until analysis. DNA was stained with 50 μl of 2 μg/ml ethidium bromide and the analysis was conducted with a fluorescent microscope (Olympus BH2-RFL). The microscope was equipped with an oil immersion Apo/Dplan 20× lens, a 515–560 nm excitation filter, a 590 nm barrier filter, and connected to a high sensitivity CDD COHU camera (0.01 lux). The final magnification was 250×. DNA lesions were quantified as Olive Tail Moment (OTM; arbitrary units) and Tail DNA using Fenestra Komet 5.5 image analysis software (Kinetics Imaging, Nottingham, UK). One hundred cells, randomly chosen, were analyzed per condition (50 cells/slide), thus a total of 100 OTM were calculated for each sample. Then, the 100 measured OTM values/sample were divided into 40 classes between the minimal and the maximal values. A non-linear regression analysis was performed on the OTM distribution frequencies with a χ^2 function model using TableCurve 2D software (version 5.0; Jandel Scientific Software, San Rafael, CA). The calculated degrees of freedom (n) for this function were a quantitative measure of the DNA-damage for a sample according to Bauer et al. [39] and Jean et al. [30]. The n, named OTM χ^2 and expressed in arbitrary units (a.u.), was used as the sole parameter for quantifying levels of DNA-damage of a sample.

2.6. Quantification by the micronucleus test of DNA-damage induced by UVA/visible and visible radiations on CHO cells

Twenty-four hours before the experiment, a total of 5×10^4 CHO cells were plated in Labtek® chamber slides and kept at 37 °C in a humidified atmosphere containing 5% CO_2. On the day of the experiment, culture medium was replaced by PBS with Ca^{2+} and Mg^{2+} and the cells were irradiated by UVA–visible or by visible light alone, as described above. The combined light doses were 15, 20, 25 and 30 J/cm^2, respectively. Assays were performed in duplicate, and a negative control maintained in the dark was included in each set of experiments. After irradiation, PBS was removed and cells were allowed to divide in the dark at 37 °C in a 5% CO_2 atmosphere in fresh culture medium for 3 h. Cytokinesis was interrupted by the addition of cytochalasin B (2 μg/ml) and the incubation was extended for 24 h. At 27 h after irradiation, cells were washed twice with PBS and submitted to a 5-min fixation step with absolute methanol. The air-dried slides were stained with 10% Giemsa in distilled water during 15 min.

The index of binuclearity (IBIN), considered as a measure of cytotoxicity, was determined by scoring the number of binucleated cells among 500 Giemsa-stained cells with well-preserved cytoplasm [40]. It was expressed as the following ratio:

$$\text{IBIN} = ((\text{mononucleated cells}) + 2 * (\text{binucleated cells}) + 3 * (\text{cells with at least 2 nuclei}))/500$$

The micronucleated cell rates were determined for concentrations inducing less than 50% toxicity; 2000 binucleated CHO were examined and micronuclei were identified according to the morphological criteria defined by Kirsch-Volders et al. [40]. Statistical differences between negative controls and irradiated samples were performed by the contingency 2 × 2 χ^2-test.

2.7. Evaluation of photoprotection by three protective compounds in human keratinocytes

Twenty-four hours prior the comet assay, the keratinocytes at approximately 80% confluence were seeded in 12-well plates at a density of 5×10^4 cells/well. On the day of the experiment, stock solutions of ectoin (4 mM), ERT (4 mM) and mannitol (12 mM) were prepared in ultrapure water. Each compound, at the required final concentrations, was added into the wells at, respectively, 0.025–0.05–0.1 mM for ectoin, 0.1–0.25–0.5 mM for ERT and 0.5–1–1.5 mM for mannitol. Culture medium alone was added for control samples. Incubation was conducted for 1 h at 37 °C. After the required incubation period, the medium was removed; the cells were washed three times with Ca^{2+} and Mg^{2+} free PBS and harvested with trypsin/EDTA for 5 min. After a centrifugation at 3000g for 5 min, cells were embedded in agarose gel and placed on microscopic slides. Immediately after the irradiation, according to the protocol described above, at a combined light dose of 15 J/cm^2, cells were submitted to the comet assay. For each experiment, controls included untreated non-irradiated cells (negative control) and untreated irradiated cells (positive control).

2.8. Evaluation of photoprotection by sunscreens in human keratinocytes

The absorption curves of the four tested sunscreens are displayed in Fig. 2. From these curves, the Sun Protection Factor (SPF) and the Protection Factor UVA (PUVA) were calculated for each sunscreen by the in vitro Diffey method [41]. SPF were 49.9 and 112.7 for Photoderm SPF 50+® and its tinted analogue, respectively, and 139.9 and 231.0 for Photoderm Max SPF100® and its tinted analogue, respectively. PUVA were 45.6 and 100 for Photoderm SPF 50+® not tinted and tinted, respectively, and 52.6 and 79.5 for Photoderm Max SPF100® not tinted and tinted, respectively. Just before irradiation, the sunscreens were uniformly spread on a quartz slide (5 × 5 cm^2) at an amount of 2 mg/cm^2 and placed above the embedded cells in the solar simulator. Slides were submitted to the alkaline comet assay immediately after the irradiation, according to the protocol described above at a combined light dose of 15 J/cm^2. Unprotected cells and non-irradiated cells were used as positive and negative controls, respectively.

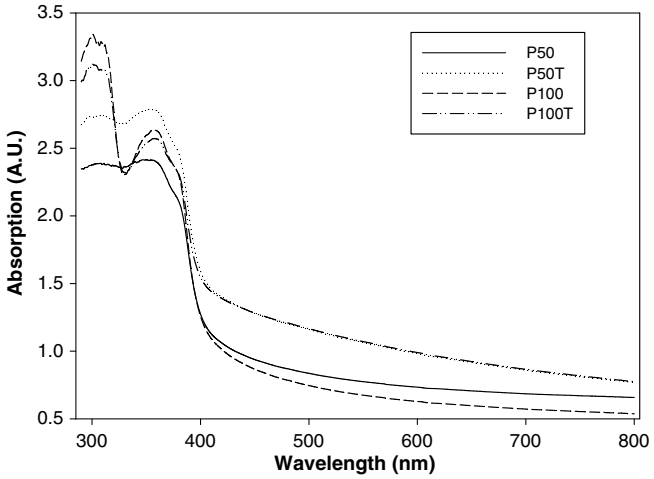

Fig. 2. Absorption spectra of Photoderm SPF 50+® (tinted and not tinted) and Photoderm Max SPF100® (tinted and not tinted) from 280 to 800 nm. Each sunscreen was spread on a quartz slide (5 × 5 cm) to reach a final amount of 2 mg/cm^2. P50: non-tinted Photoderm SPF 50+®. P50T: tinted Photoderm SPF 50+®. P100: non-tinted Photoderm Max SPF100®. P100T: tinted Photoderm Max SPF100®.

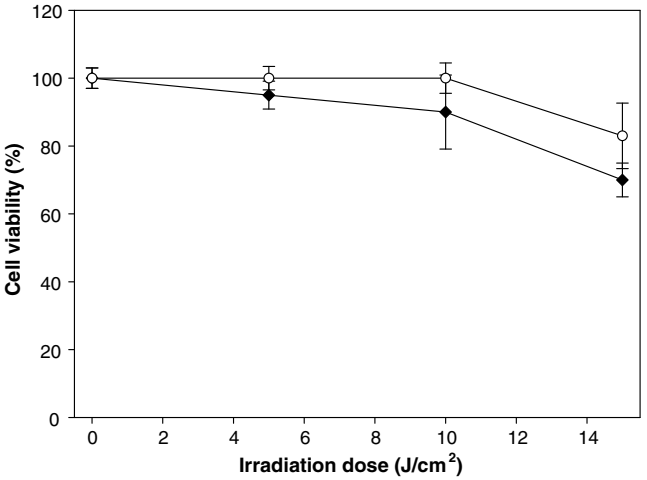

Fig. 3. Viability of human keratinocytes irradiated with increasing doses of UVA/visible light (5–15 J/cm^2) with (○) and without (♦) the visible filter. The cell viability was measured 30 min after irradiation by the WST-1 assay and the results are expressed as a percentage of the reading in control wells. Each point represents the mean ± SE of four measures.

3. Results

3.1. Cytotoxicity induced by exposure to UVA/visible and visible light in normal keratinocytes

Keratinocytes were irradiated with increasing doses of UVA/visible light (5–15 J/cm^2) with and without the visible filter. The cell viability was determined 30 min after irradiation by the WST-1 assay. Results are expressed as percentage of cell viability in reference to the control (non-irradiated keratinocytes), which corresponds to 100% cell viability. The results are included in Fig. 3. A slight decrease in cell viability was observed after irradiation by UVA/visible. For the highest irradiation dose (15 J/cm^2), the decrease of the cell viability was 30%.

The viability of cells was not affected by irradiation with visible light except for the higher tested dose (13.8 J/cm^2) which slightly reduced the cell survival by approximately 17%.

3.2. Induction of DNA-damage by UVA/visible and visible radiations on human keratinocytes measured by the alkaline comet assay

Keratinocytes embedded in agarose were irradiated at increasing doses of UVA/visible (5–15 J/cm^2) with or without the visible light filter in the solar simulator, then immediately submitted to the comet assay to avoid DNA repair processes. Because primary human keratinocytes showed variability in their response to UVA and visible light, an

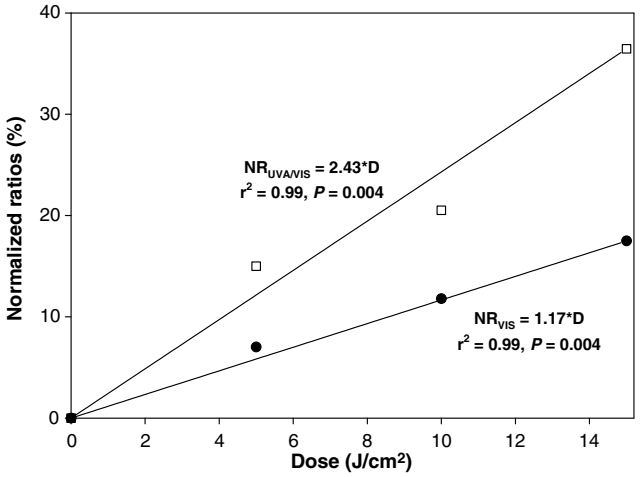

Fig. 4. Dose–response relationship of DNA-damage versus UVA/visible and visible irradiation in human keratinocytes measured by the comet assay. Cells were irradiated at increasing dose of UVA/visible 5–10 J/cm^2 with and without visible filter, then immediately submitted to the comet assay. The OTM χ^2 are expressed as normalized ratios, according to the following formula:

$$\text{ratio} = \frac{\left(\text{OTM } \chi^2_{\text{sample}} - \text{OTM } \chi^2_{\text{NI}}\right)}{(\text{OTM } \chi^2_{\text{MMS}} - \text{OTM } \chi^2_{\text{NI}})} * 100$$

where OTM χ^2_{sample} is the OTM χ^2 of the irradiated sample; OTM χ^2_{MMS} the OTM χ^2 of the treated sample with 60 μM methyl-methane-sulfonate (positive control); OTM χ^2_{NI} is the OTM χ^2 of the non-irradiated sample (negative control). White squares: UVA/visible light; black circles: visible light only.

internal standard, namely the alkylating agent methyl-methane-sulfonate, was included for each tested irradiation dose. Complete results concerning the DNA-damaging effects of UVA/visible and visible radiations on human keratinocytes are reported in Table 1. DNA strand-break induction was significant at the lowest irradiation dose of 5 J/cm^2, with OTM χ^2 of 4.78 ± 0.79 for UVA/visible light and OTM χ^2 of 3.78 ± 1.00 for visible light. It dramatically increased between 10 and 15 J/cm^2, with OTM χ^2 reaching 9.37 ± 0.31 and 5.91 ± 0.21 for UVA/visible and visible radiations, respectively, at the highest irradiation dose. Normalized ratios (%) are illustrated in Fig. 4. Significant increases in DNA strand breaks were calculated after irradiation by UVA/visible and visible light, in a linear dose–response model ($r^2 = 0.99$, $P = 0.04$ for both UVA/visible and visible light). Slope comparison of the curves showed that the genotoxic effects of visible light represented around 50% of the total effects of UVA/visible irradiation (with slope values of 1.17 and 2.43 a.u., respectively).

3.3. Induction of DNA-damage by UVA/visible and visible radiations on CHO cells measured by the micronucleus test

Micronucleus test was carried out on CHO cells irradiated by UVA/visible and visible light at four increasing doses (15–30 J/cm^2). CHO cells were selected for this series of experiments because of their high capacity to divide as compared to human normal keratinocytes. Complete results are reported in Table 2. Both UVA/visible and visible radiations produced a dose-dependent increase of micronuclei rates. Micronuclei induction was significant at the lowest irradiation dose tested (15 J/cm^2) with 24.5 ± 4.9 micronucleated cells per 1000 observed after UVA/visible irradiation and 18 ± 1.4 micronucleated cells observed after visible irradiation. This genotoxic activity was maximal after an irradiation dose of 30 J/cm^2, with micronucleated cell rates reaching $37 \pm 2.8‰$ and $26.5 \pm 2.1‰$ for UVA/visible and visible light, respectively. The micronuclei induction rates of visible light represented approximately 60% of the global effects of UVA/visible irradiation, demonstrating that visible light could induce chromosome rearrangements.

3.4. Evaluation of the protective effects of ectoin, ERT and mannitol

Keratinocytes were incubated 1 h at 37 °C in culture medium with various concentrations of each compound. Embedded cells were submitted to irradiation by UVA/visible or visible radiations. The irradiation dose was fixed at

Table 2
Micronuclei induction by UVA/visible and visible light in CHO cells

Dose (J/cm^2)	Sample	Binucleated cells	Mononocleated cells	IBIN	IBIN (%)	MNC (‰)
0	NI	486.5 ± 3.5	13.5 ± 3.5	1.95	100	7.5 ± 0.7

*** $P < 0.001$ by the 2×2 χ^2 contingency test.

15 J/cm^2 throughout the experiments. Immediately after the irradiation, slides were immersed in lysis solution for the continuation of the comet assay.

For the three tested molecules, the highest concentration showed neither cytotoxicity nor DNA-damaging activity as evaluated by the trypan blue staining (data not shown). Three concentrations of ectoin were tested: 0.025, 0.05 and 0.1 mM. Results are illustrated on Fig. 5. All the tested concentrations showed a highly significant level of photoprotection against UVA/visible light and visible light with a dose–response relationship. At 0.1 mM, the OTM χ^2 were 2.37 ± 0.41 and 4.04 ± 0.16 for visible and UVA/visible irradiations, respectively, corresponding to 92.7% and 68.9% levels of photoprotection.

The effects of ERT on DNA SSB induced by UVA/visible and visible radiations are reported in Fig. 6. Three concentrations of ERT were tested: 0.1, 0.25 and 0.5 mM. Two concentrations exerted a significant protection against UVA/visible light, and a maximal protection rate of 59.8% was obtained at the concentration of 0.5 mM, with an OTM χ^2 value of 5.15 ± 0.20. The protective activity of ERT against visible radiations was more efficient, with a maximal protection rate reaching 97.9% at the concentration of 0.5 mM, with an OTM χ^2 value of 2.29 ± 0.19.

Mannitol exerted a significant dose-dependent photoprotection against UVA/visible radiations (Fig. 7): the lowest concentration (0.5 mM) decreased the OTM χ^2 value at 11.93 ± 0.40 corresponding to a statistically significant protection of 16.9%. A maximal protection rate of 62.7% could be observed at 1.5 mM, with an OTM χ^2 value of 6.71 ± 0.29. The protective activity of mannitol against visible radiations was lower since the calculated protection rates were no statistically significant (2.6% and 13.8%) at the concentrations of 0.5 and 1 mM, respectively. However, a statistically significant 52.0% protection rate was obtained at the concentration of 1.5 mM, with an OTM χ^2 value of 5.18 ± 0.19. These results overall demonstrated that the presence of endogenous protective compounds during UVA/visible or visible irradiation led to a significant protective effect against DNA-damage. They also indicated that the efficacy of the protection depended on the nature of both the molecules and the radiations.

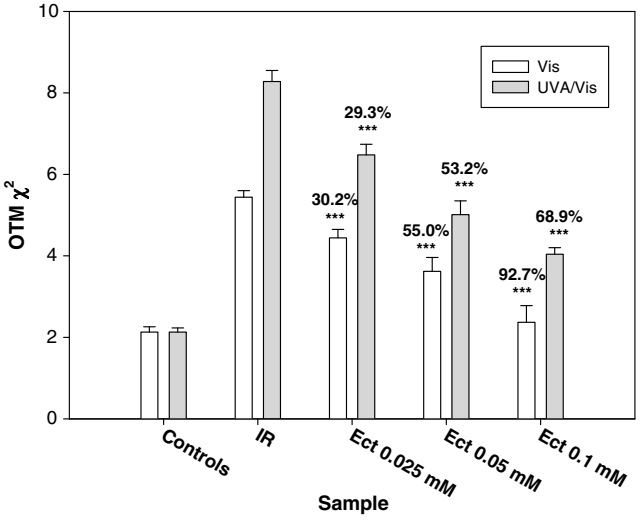

Fig. 5. Photoprotection of ectoin on human keratinocytes measured by the alkaline comet assay. Cells were incubated for 1 h at 37 °C with ectoin (0.025–0.1 mM) and were irradiated with a combined light dose of 15 J/cm^2 (corresponding to 1.2 J/cm^2 UVA and 13.8 J/cm^2 visible) with or without visible filter. After irradiation, cells were immediately submitted to the comet assay. Control: non-irradiated cells; IR: untreated irradiated cells; NS: non-significant; $^{***}P < 0.001$.

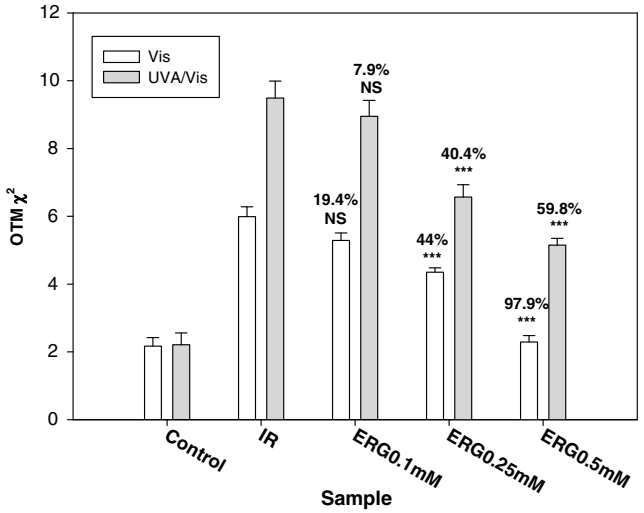

Fig. 6. Photoprotection of ERT (0.1–0.5 mM) on human keratinocytes measured by the alkaline comet assay. Experimental conditions are described in the legend of Fig. 4. Control: non-irradiated cells. IR: untreated irradiated cells. NS: Non-significant. $^{***}P < 0.001$.

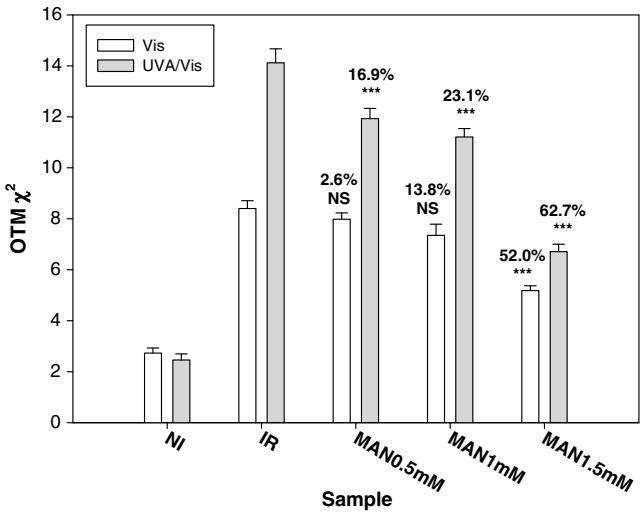

Fig. 7. Photoprotection of mannitol (0.5–1.5 mM) on human keratinocytes measured by the alkaline comet assay. Experimental conditions are described in the legend of Fig. 4. Control: non-irradiated cells. IR: untreated irradiated cells. NS: Non-significant. $^{***}P < 0.001$.

3.5. Evaluation of photoprotective effects of broad-spectrum sunscreens

Sunscreens were evenly spread on quartz slides at 2 mg/cm^2 before irradiation. The irradiation dose was fixed at 15 J/cm^2 throughout the experiments. Embedded keratinocytes were submitted to irradiation as described in the previous section, protected or not by sunscreens, and directly immersed in lysis solution.

The protective effects of sunscreens against DNA-damage induced by UVA/visible and visible light, as assessed by the comet assay on human keratinocytes, are reported in Fig. 8. The four sunscreens (Photoderm SPF 50+®, tinted Photoderm SPF 50+®, Photoderm Max SPF100® and tinted Photoderm Max SPF100®) significantly reduced the DNA-damaging activities of UVA/visible and visible radiations. Photoderm SPF 50+® and Photoderm Max SPF100® exhibited protection rates of 79.9% (OTM $\chi^2 = 3.64 \pm 0.23$) and 86.7% (OTM $\chi^2 = 3.14 \pm 0.15$), respectively, against UVA/visible light, while their tinted analogues appeared more active, with protection rates of 92.6% (OTM $\chi^2 = 2.69 \pm 0.22$) and 97.1% (OTM $\chi^2 = 2.40 \pm 0.21$), respectively. Similarly, a high photoprotective activity against visible light could be obtained: Photoderm SPF 50+® and Photoderm 100+® exerted a protection rate of 82.8% (OTM $\chi^2 = 2.77 \pm 0.24$) and 92.5% (OTM $\chi^2 = 2.47 \pm 0.24$), respectively, while their tinted analogues both displayed a 100% protective effect (OTM $\chi^2 = 2.12 \pm 0.08$ and 2.16 ± 0.12, respectively). These results indicated that sunscreens could efficiently prevent DNA-damage induced by both UVA/visible and visible lights, and implied that tinted ointments exerted a higher protective activity than their colorless counterparts.

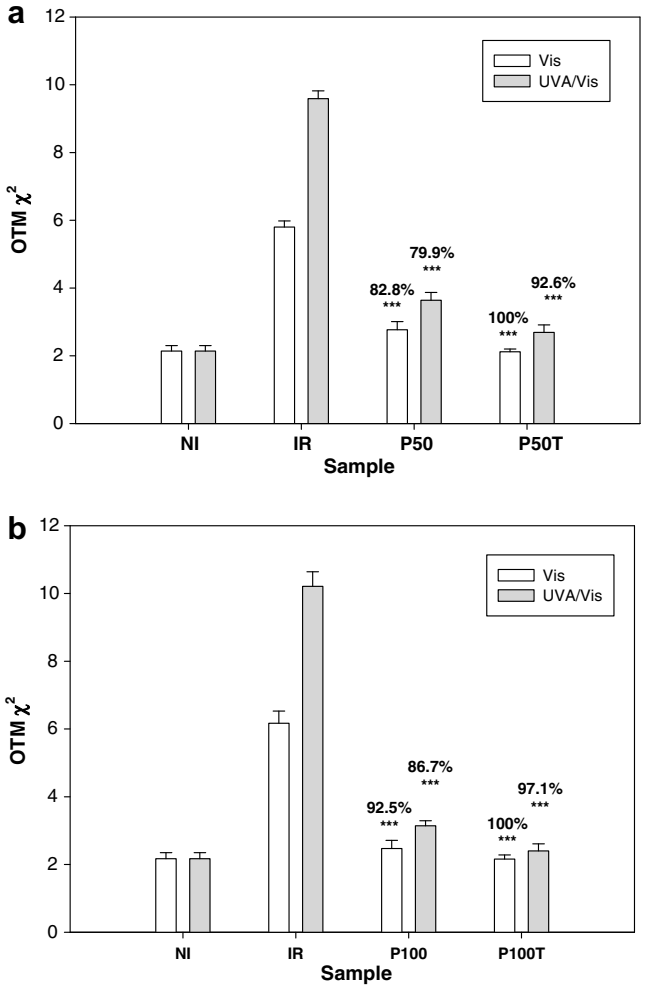

Fig. 8. Photoprotection of sunscreen Photoderm SPF 50+® (tinted and not tinted, A) and Photoderm Max SPF 100® (tinted and not tinted, B) measured by the comet assay. Keratinocytes were irradiated with a combined light dose of 15 J/cm^2 (corresponding to 1.2 J/cm^2 UVA and 13.8 J/cm^2 visible) and immediately submitted to the comet assay. NI: non-irradiated control. IR: unprotected irradiated cells. P50: irradiated cells protected by Photoderm 50+®. P50T: irradiated cells protected by tinted Photoderm 50+®. P100: irradiated cells protected by Photoderm Max 100+®. P100T: irradiated cells protected by tinted Photoderm Max 100+®.

4. Discussion

Solar radiations, especially UVA and UVB, are known to induce DNA lesions that may lead to carcinogenesis. If UVB radiations directly alter nuclear DNA, UVA are weakly absorbed by DNA and induce indirect DNA-damage by excitation of endogenous chromophores [42]. Little is known about the genotoxic effects of visible light (400–800 nm). The distinction between UVA and visible radiations is an artificial criterion. As a possible consequence, photobiological effects of the long UVA region and the near visible radiations (between 400 and 450 nm) could overlap [22].

In this study, the alkaline comet assay was performed to evaluate the genotoxic effects of visible light on human normal keratinocytes. These cells showed high variability in their responses to irradiation, because primary cells cultures were obtained from different human donors and the cells were in different growth stages at the time of the experiment. Moreover, the experimental variability inevitably induced an additional heterogeneity of the responses. This underlined the necessity of using internal standard for each irradiation dose as suggested by De Boeck et al. [43]. Keratinocytes were submitted to irradiations by UVA/visible (315–800 nm) with and without a visible light filter. Results showed that visible light induced statistically significant DNA SSB for all the tested doses of irradiation. The present results are consistent with the previous finding of Singh et al. [44]. The authors showed that visible light could induce DNA SSB and alkali-labile sites in rat lens epithelial cells and in human lymphocytes, as assessed by the comet assay. In our study, a linear dose–response relationship was observed between irradiation doses and normalized DNA lesions, for both UVA/visible and visible light. The level of DNA breakage induced by visible light was 50% of the one generated by UVA/visible irradiation. Thus, visible light is able to induce as much DNA breaks as UVA radiations. However, for a combined light dose of

15 J/cm^2, visible and UVA light represent a dose of 13.8 and 1.2 J/cm^2, respectively. Thus, UVA radiations are 10 time more effective than visible radiations to induce DNA SSB. Moreover, most of the energy delivered by the xenon lamp (Fig. 1) is concentrated between 450 and 500 nm, suggesting a possible implication of near-visible radiations in genotoxic lesions.

Our comet assay methodology involved the detection of direct DNA breakage (cell lysis performed immediately after the irradiation) [45]. Thus, the SSB detected by the comet assay reflected direct UVA-induced DNA lesions that were mainly produced by ROS [45,46]. Our results are consistent with this mechanism. It could be hypothesized that DNA-damage observed after irradiation of keratinocytes by visible light may also be generated by the same process than UVA rays. This has been previously demonstrated by Kielbassa et al. [47]: after irradiation of CHO cells by UV/visible light, the maximal rate of formamidopyrimidine–DNA glycosylase (Fpg)-sensitive lesions (i.e. 8-oxodG and formamidopyrimidines) was observed between 400 and 450 nm. These oxidative lesions could be due to the excitation of endogenous photosensitizers. These results have been confirmed in 1998 by Pflaum et al. [25] in HaCaT and primary keratinocytes: most of the oxidative DNA base modifications were generated in the visible range of sunlight. Moreover, these lesions could be the consequence of photoactivation of cellular porphyrins, because their maximal excitation wavelength is 406 nm. Other potential intracellular chromophores, such as flavins, that possess peaks absorption between 334 and 434 nm, could be involved in photosensitization mechanisms [48].

The chromosomal mutagenicity of visible light was investigated by the micronucleus test on the rapid growing cell line CHO. We found a non-linear dose-related induction of MNs after irradiation by both UVA/visible and visible light. UVA radiations have been shown to induce a dose-dependent formation of MNs in human fibroblasts at a dose range of 10–30 J/cm^2 [49]. Likewise, an increase of MNs and a persistent genomic instability have been found in HaCaT cells after UVA irradiation (10 J/cm^2) [50]. Visible light has also been shown to induce MNs formation in melanoma cell line and primary human skin fibroblasts [51]. Several mechanisms have been suggested for the induction of MNs by UVA and visible light: (i) oxidative damage through photosensitization processes [25] or redox status alteration [50]; (ii) generation of double strand breaks through the propagation of clustered single-strand breaks [52]; (iii) epigenetic mechanisms, such as DNA–protein crosslinks or lesions of the mitotic spindle elements [51]. Further studies would be necessary to apprehend most clearly these mechanisms.

To evaluate the importance of oxidative damage in UVA/visible and visible irradiations, we assessed the photoprotective effects of three exogenous compounds (ectoin, ERT and mannitol) on human keratinocytes by the comet assay. All the tested molecules exerted an effective dose-dependent DNA protection against both UVA/visible and visible light. These results strongly suggested the implication of ROS in the visible-induced genotoxicity, as for UVA-induced DNA lesions. Ectoin is a cyclic tetrahydropyrimidine, produced by halophilic eubacteria [53]. This natural substance has been shown to prevent UVA-induced cell damage, by the reduction of pro-inflammatory gene expression such as ICAM-1 and by the expression of heat shock proteins 70 (Hsp70s) that protect cells against heat stress and toxic chemicals [53,54]. ERT (2-mercaptohistidine trimethylbetaine) is a low-molecular-mass thiol that is synthesized in microorganisms, and can be found in some human tissues after dietary intake [55]. This molecule has been shown to possess intrinsic anti-hydroxyl radical (•OH) activity [56] and to exert protective effect against UVA radiations [26]. Similar properties have been demonstrated for mannitol, which appeared to be an effective hydroxyl radical quencher [57].

In the last part of this study, we evaluated the ability of four broad-spectrum sunscreens to protect human keratinocytes against UVA/visible and visible light genotoxicity by the alkaline comet assay. The tested sunscreens revealed an effective photoprotection against UVA/visible and visible radiations by reducing the extent of DNA breakage. For the two sunscreens, the tinted formulations demonstrated higher effective genomic photoprotection against both UVA/visible and visible light. Most commercialized sunscreens afford effectiveness against UVB and UVA, but do not give significant protection against visible radiations [58]. A small number of tinted sunscreens are already used by photosensitive patients: these formulations contain large-sized particles of titanium dioxide (pigment grade) and zinc oxide that scatter visible radiations [58]. Our study underlies the necessity of an extended protection in the visible range. It focuses on the development of new formulations that would produce an improved protection against visible light and an enhanced cosmetic acceptability.

In conclusion, this study revealed the genotoxic effects of visible light (400–800 nm) as assessed by the comet assay and the micronucleus test. These effects appeared to be mediated by oxidative stress mechanisms similar to the ones produced by UVA radiations. Moreover, our results emphasize the need to complement sunscreen formulations with internal protective compounds to afford internal photoprotection and with additional molecules that remain to be characterized, to obtain a complete external photoprotection against UVA and visible light.

5. Abbreviations

Abstract

Alcohol use disorders affect millions of individuals worldwide. Alcohol consumption is directly associated with liver disease mortality and accounts for elevated social and economic costs. Alcoholic liver disease (ALD) may take the form of acute involvement (alcoholic hepatitis) or chronic liver disease (steatosis, steatohepatitis, fibrosis and cirrhosis). The severity and prognosis of alcohol-induced liver disease depends on the amount, pattern and duration of alcohol consumption, as well as on the presence of liver inflammation, diet, nutritional status and genetic predisposition of an individual. While steatosis is an almost completely benign disease, liver cirrhosis is associated with marked morbidity, mortality and life expectancy shortening. The median survival of patients with advanced cirrhosis is 1-2 years. Severe acute alcoholic hepatitis (AH) is associated with mortality as high as 50%. It has been managed with corticoids, pentoxifylline and enteral nutrition, although evidence based data are still conflicting. Some author suggest that pentoxifylline could be a better first-line treatment in patients with severe AH. Absolute abstinence is a basic condition for any treatment of acute or chronic ALD, the other therapeutical procedure being of a supportive nature and questionable significance. Acamprosate appears to be an effective treatment strategy for supporting continuous abstinence in alcohol dependent patients. Patients with advanced liver cirrhosis who demonstrably abstain can be considered for liver transplantation, which leads to a markedly prolonged life expectancy. The crucial step in ALD prevention is in the prevention of alcohol abuse, whereas the prevention of liver injury in active alcohol abusers is not clinically applicable.

Key words: Alcohol; Alcoholic liver disease; Liver cirrhosis; Liver fibrosis; Steatohepatitis; Steatosis

INTRODUCTION

Alcohol is a most frequent cause of liver disease in western countries[1]. Mortality due to liver cirrhosis in those countries is in direct proportion to absolute alcohol consumption per capita-the highest in France and Spain (over

30 deaths per a population of 100 000 per year), the lowest in the northern European countries (up to 5 deaths per 100 000 inhabitants per year). In Central Europe, the figure is 15 deaths due to cirrhosis per 100 000. The highest mortality is in men aged 35-64 years, lower in women (Figure 1)[2]. The past two to three decades have seen a stabilization if not a drop in the intake of alcohol in western countries, while a very adverse trend is reported from Eastern Europe and developing countries[3].

In what is an alarming development, alcohol abuse also afflicts societies and nations without any "drinking tradition", such as in Asia. For example, in a cross-sectional study of two rural communities in China (in which almost 10 000 inhabitants were interviewed for current and lifetime alcohol use)[4], the age-standardized prevalence of lifetime alcohol dependence ranged from 4.8% to 11.8% in different regions. Unlike most western reports, alcohol dependence shows a higher prevalence than the abuse itself.

Coincidence with HIV infection is another attribute of alcohol abuse. This was described in India for example, where the recent increase in alcohol consumption in many sectors of the general population is coupled with strong evidence of the role of alcohol in the spread of HIV infection and other health risks[5]. An even more critical situation appears to have developed in Africa. Pithey *et al*[6] performed a systematic review of sub-Saharan African studies concerning the association between alcohol abuse and HIV infection. Their findings strongly support an association between the two factors. A Fisher *et al*[7] study of high-risk African women showed, even after adjustment for demographic and employment variables, that drinkers were more likely to be HIV positive than non-drinkers (relative risk 2.1). Problem drinkers were also more likely to have engaged in several types of high-risk sexual behavior and to have other sexually transmitted infections, including HSV-2.

Many studies have shown that the amount of undiluted ("pure") alcohol consumed and the duration of that consumption are closely related to cirrhosis. According to some reports, cirrhosis does not develop below a lifetime alcohol consumption of 100 kg of undiluted alcohol[8]. This amount corresponds to an average daily intake of 30 grams of undiluted alcohol for 10 years. Heavy alcoholics consuming at least 80 g of alcohol per day for more than 10 years will develop liver disease at a rate of nearly 100%. A detailed study of 256 heavy drinkers admitted to hospital not because of liver complaints, found steatosis at a rate of 45%, steatohepatitis at 34%, steatohepatitis with cirrhosis at 10% and cirrhosis alone at 10% in their liver biopsies[9]. Formerly, 40-60 g of undiluted alcohol (i.e., 2-3 beers) per day used to be reported as a safe limit for men, less (20 g/d) for women. Data from the "Dionysos" study show, however, that consumption of more than 30 g of pure alcohol daily, regardless of sex, already increases the risk of liver disease[10].

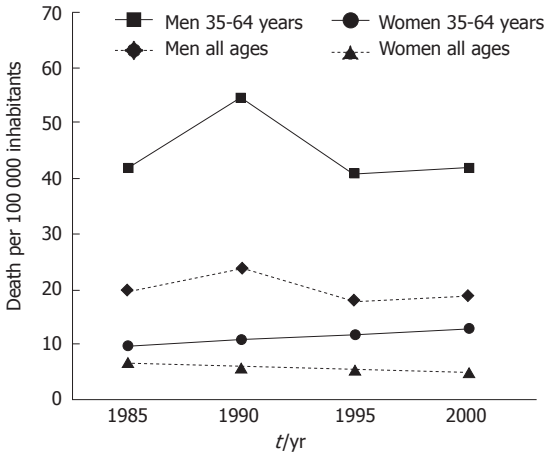

Figure 1 Mortality from cirrhosis in Czech Republic[2].

For practical purposes, alcohol intake is rated by the count of "drinks". The National Institute on Alcohol Abuse and Alcoholism defines a standard drink as 11-14 g of alcohol, which corresponds to approximately one drink of 40% spirit, one glass of wine or one 0.33 l (12-oz) beer. Hence, a "safe" daily intake of alcohol should not be more than two "drinks". On the contrary, moderate ethanol consumption (mainly wine) may mean a reduced cardiovascular risk[11], especially in women[12].

Much the same applies to Asians. For example, in the Chinese population, the ethanol risk threshold for developing alcoholic liver disease (ALD) is 20 g per day with the risk increasing in proportion to the daily intake[13]. Those drinking 20 g of ethanol per day and for less than 5 years are safe from ALD. In this study of 1270 alcohol drinkers, obesity also increases the risk. Abstinence and weight reduction will directly improve the prognosis of ALD.

As for liver injury, it has been postulated for many years that the type of alcoholic beverage makes little, if any difference. Nevertheless, some authors have proposed that mortality from cirrhosis is associated with the consumption of spirits more strongly than with other alcoholic beverages[14]. It is not clear whether this effect can be put down to the drinkers' socio-behavioral characteristics or to increased toxicity of alcoholic beverages[15].

ALD may take the form of acute involvement (alcoholic hepatitis) or chronic liver disease (steatosis, steatohepatitis, fibrosis and cirrhosis). Their progression also depends on the pattern of alcohol intake-drinking alcohol at mealtimes results in a lower risk of liver disease than consumption at other times; fitful, intermittent drinking is more sparing for the liver than a continuous supply of alcohol[16].

Although ALD is a disease that displays an absolute requirement for a voluntary environmental exposure (the consumption of alcohol), many other factors, including genetic host system attributes, are involved in the ALD evolution and progression.

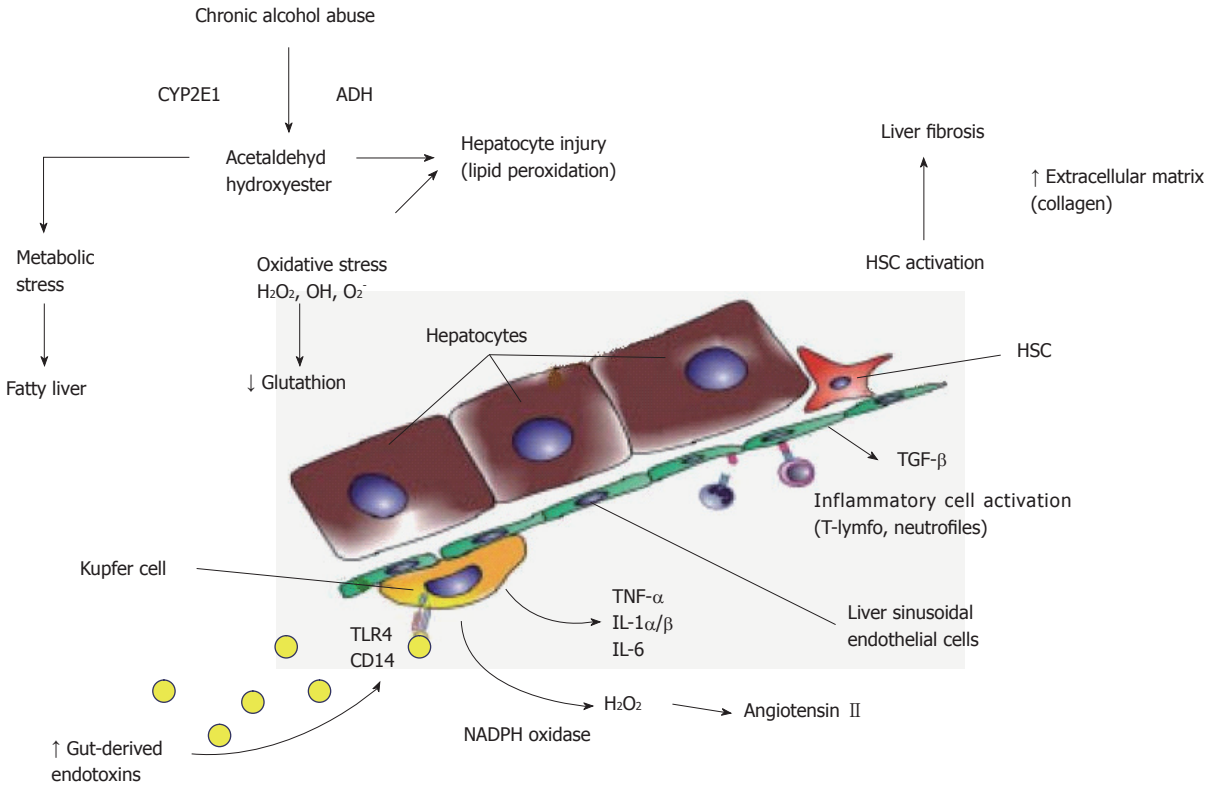

Figure 2 Pathogenesis of inflammatory changes in alcoholic liver disease[56]. ADH: Alcohol dehydrogenase; HSC: Hepatic stellate cell.

ETIOLOGY, PATHOGENESIS, NATURAL COURSE AND PROGNOSIS OF ALCOHOLIC LIVER DISEASE

The liver is the main organ of alcohol metabolism. Alcohol is metabolized in the liver in three ways: (1) by the enzyme alcohol dehydrogenase (ADH); (2) by cytochrome P-4502E1 (CYP2E1); and (3) by mitochondrial catalase. Only the first two pathways are of practical significance-ADH finds use in the degradation of limited quantities of alcohol, while alcohol-induced CYP2E1 takes place in excessive alcohol intake. Apart from the liver, ADH is also present in the gastric mucosa and the assumption is that individuals with low gastric ADH activity are more susceptible to alcoholic liver disease. This may also help to explain why women who have decreased gastric ADH activity[17] are more susceptible to developing alcoholic liver disease.

Both enzymes convert alcohol to acetaldehyde, which is in part responsible for the liver injury too. However, the process of liver injury is much more complex (Figure 2)-resulting from biochemical, genetic, cellular, immunological and humoral disorders in connection with the intake and metabolism of excessive quantities of alcohol. A major role is played there by oxidative stress (which is mainly due to alcohol-induced CYP2E1), by simultaneous shortage of antioxidants in the hepatocytes and, last but not least, by acetaldehyde alone and altered balance of many cytokines-mainly tumor necrosis factor (TNF)-α[18]. Changes in lipid metabolism and in adipose tissue also enhance the process of liver injury[19]. All above mentioned changes result in the injury of cell membranes and organelles (especially mitochondria). The mechanisms of hepatocytic damage due to excessive intake of alcohol show some similarity to changes seen in non-alcoholic steatohepatitis, except that the primary insult is different[20].

Individual susceptibility is another factor to take into account; moreover, any other liver involvement such as viral hepatitis[21] or metabolic disease adds to the risks of alcoholism, as does obesity and metabolic syndrome[22].

In fact, alcoholics were clearly shown to have an increased prevalence of HCV when compared with non-alcoholics and this combination synergistically accelerates liver injury[23]. As for alcohol influence on the liver, the caloric intake should also be taken in account. Increased caloric intake leads to excessive fat deposition and obesity in some patients and can aggravate the liver injury[24].

Of late, there has been an influx of information on correlations between genetic polymorphisms of alcohol-metabolizing enzymes and alcoholic liver disease[25]. The genetics of ALD development involves an inherited predisposition to alcohol dependence, as well as the resulting development of liver injury[26]. Family studies have established an important role of genetics in alcohol dependence. To date, only two genes, which are involved in alcohol metabolism, have shown significant involvement. The alcohol dehydrogenase ADH1B*1 allele was found to be associated with an approximately threefold increase in alcohol dependence and the aldehyde dehy-

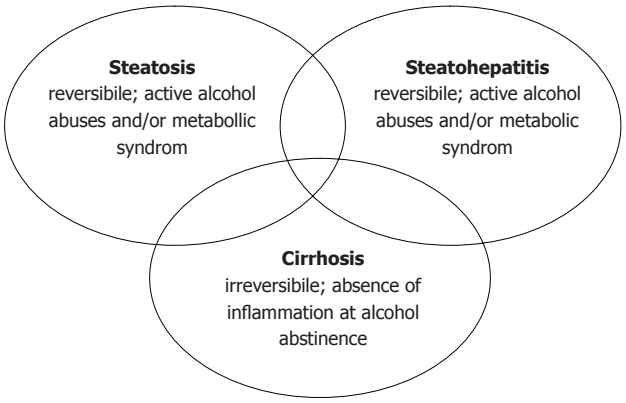

Figure 3 Spectrum of alcoholic liver disease.

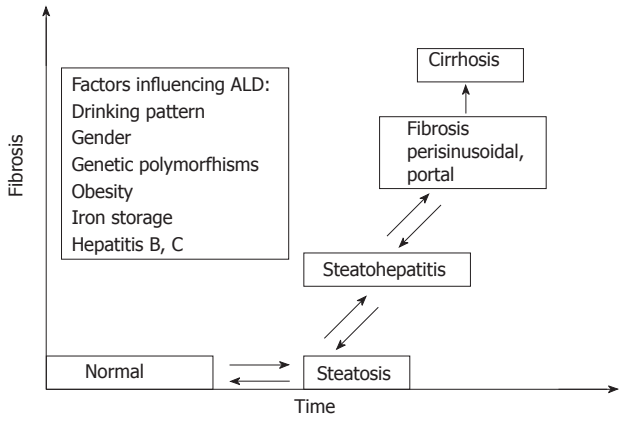

Figure 4 Dynamic process of alcoholic liver disease. ALD: alcoholic liver disease.

drogenase ALDH2*2 allele was found to be instrumental in a 10-fold reduction of the alcohol dependence risk[27]. This association was described in Asian populations[28]. Also reported have been links between alcohol dependence and certain genetic polymorphisms of genes for the GABA receptor or some other neuropeptides[29].

Although most heavy drinkers do develop fatty liver, only a minority progress to liver cirrhosis, suggesting that some other genetic or environmental factors are important for the disease progression. Evidence of genetic involvement in the progression of alcoholic fatty liver to advanced ALD comes from a twin study. The rate of alcoholic cirrhosis was described to be significantly higher in monozygotic twins than in dizygotic twins (16.9% *vs* 5.3%, respectively)[30]. A study of genes involved in alcohol metabolism (e.g., alcohol and aldehyde dehydrogenase and cytochrome P450 2E1) and genes associated with inflammation (e.g., TNF-α and interleukin-10) proved to be inconclusive, with several allelic associations detected but not verified in follow-up studies[31]. The Asian population's hypersensitivity to alcohol could be put down to polymorphisms of genes for the enzymes ADH and CYP2E1. Perhaps the most compelling genetic finding for advanced ALD risk involves the immune regulatory cytotoxic T lymphocyte antigen-4 gene, in which homozygosity for the A49G polymorphism was found to confer a significant risk of alcoholic cirrhosis (odds ratio 3.5) in Italians[32]. However, this finding has yet to be confirmed in follow-up studies.

Polymorphisms for TNF-α co-responsible for an increased risk of liver disease have been discovered in a similar way[33]. For the time being, though, we do not know how to make use of this new knowledge in routine practice.

Malnutrition is another clinical situation with an impact on the evolution of ALD. Heavy alcohol drinkers often lack proper diets or consume diets which are compromised in various nutrients, such as proteins, polyunsaturated fatty acids and vitamins[34].

Liver steatosis is the most frequent primary change in chronic alcohol abuse. Changes associated with alcohol metabolism may subsequently trigger an inflammatory reaction, resulting in alcoholic hepatitis or chronic liver disease (Figure 3).

Liver disease in alcohol abusers is more likely to take the form of chronic changes (steato-hepatitis and fibrosis), leading to cirrhosis later in life. The spectrum of histological findings can be described as a dynamic process[35] (Figure 4). Simple steatosis is reversible after a number of weeks of abstinence; steatohepatitis, a condition seen in only some alcoholics, is a fibrogenic process which can induce changes leading to cirrhosis. Steatohepatitis is also reversible, although a certain degree of fibrosis may persist. The reversibility of steatohepatitis or even fibrosis in humans is well documented by trials on the treatment of chronic hepatitis C[36] and experimentally on NASH models[37]. Steatohepatitis, in particular, often coincides with liver cirrhosis in active alcoholics and is a frequent cause of decompensation of cirrhosis[38].

Simple steatosis is regarded as a benign condition; nevertheless, given continued abuse, it too, can induce fibrogenesis[39]; in any case, up to 20% of the patients with simple steatosis are likely to develop fibrosis or cirrhosis within a period of ten years[40]. The prognosis of a patient with cirrhosis depends mainly on the presence of complications because of portal hypertension and continued abuse of alcohol. Abstainers with decompensated cirrhosis have a five year survival at a rate of 60% against the 30% survival rate in those who continue in the abuse[41].

Severe alcoholic hepatitis, although relatively rare, has a death rate of up to 50%. Identifying individuals with a high mortality risk is crucial in the management of acute alcoholic hepatitis. Multiple prognostic factors were studied over the last decade, including Child-Pugh classification (CTP), Maddrey score (bilirubin mg/dL + 4.6 × prothrombin time)[42] and others. The MELD score was found a more valuable model than CTP or the Maddrey score in the detection of high risk patients admitted with alcoholic hepatitis[43]. Alternatively, the more recent Glasgow alcoholic hepatitis score could be used[44]. A Glasgow score exceeding 9 points is associated with poor prognosis (Table 1).

Table 1 Glasgow alcoholic hepatitis score[44]

Parameter/score	1	2	3
Age (yr)	< 50	⩾ 50	-
Leucocytes (10^9/L)	< 15	⩾ 15	-
Urea (mmol/L)	< 5	⩾ 5	-
INR	< 1.5	1.5-2	> 2
Bilirubin (μmol/L)	< 125	125-250	> 250

The score is to be added to each parameter, the sum total being between 5 and 12 points. The value of 9 and higher implies poor prognosis in alcoholic hepatitis. **INR: International normalised ratio.**

CLINICAL MANIFESTATION AND LABORATORY FINDINGS

Patients with steatosis are usually symptom-free; they may have slightly elevated liver function tests and enlarged liver (both are often discovered accidentally during examination for other reasons).

In the stage of acute alcoholic hepatitis, there may be nausea, loss of appetite, gradual loss of weight, icterus and other symptoms of liver dysfunction (prolonged prothrombin time, hypoalbuminemia, ascites, and hepatic encephalopathy). Patients with alcoholic hepatitis usually show increased liver test results, including gamma-glutamyl transferase (GGT), hypergammaglobulinemia and enlarged liver.

Sonography is the basic imaging technique for liver examination. Liver biopsy, while not always necessary, can help to differentiate simple steatosis from steatohepatitis, fibrosis or incipient cirrhosis. Precise definition of the liver fibrosis stage is essential for management and prognosis in clinical practice. Recently, blood markers and instrumental methods have been proposed for non-invasive assessment of liver fibrosis[45]. However, there are still some doubts as to their implementation in clinical use. Non-invasive examination with transient elastography takes advantage of the fibrotic liver tissue ability to change the velocity of ultrasound propagation. The results of this method correlate well with the bioptically proved degree of fibrosis[46]. Similar results could be obtained from a combination of biochemical and clinical parameters of fibrosis. As for the clinical picture, the state of alcoholic liver cirrhosis shows no difference from cirrhosis of other etiology[38].

ASSESSMENT OF ACTIVE ALCOHOL ABUSE

Assessment of continued alcohol abuse in patients with alcoholic liver disease is essential for their treatment as well as prognosis. Those with alcoholic cirrhosis also make up a significant part of patients indicated for liver transplantation (30%-50%), bearing in mind that abstinence is an essential condition for considering this treatment. Continued alcohol abuse is evaluated on the basis of clinical history, psychological examination and laboratory testing. Thorough clinical and psychological examination is the crucial condition for alcohol abuse diagnosis. Regarding the clinical history, the diagnosis of alcohol abuse and dependence was substantially improved by implementation of simple methods such as a single question inquiring how often the maximum daily alcohol limit has been exceeded[47]. Other clinical screening tools such as the need to cut down, annoyed by criticism, guilty about drinking need for an eye-opener in the morning (CAGE), and the alcohol use disorders identification test (AUDIT-C) are also very easy to apply[48]. With the CAGE questionnaire, two positive answers indicate alcohol dependence with a sensitivity of more than 70% and specificity of more than 90%. The AUDIT-C screening thresholds for the detection of alcohol abuse are ⩾ 4 points for men (sensitivity 86%, specificity 89%) and ⩾ 3 points for women (sensitivity 73%, specificity 91%).

As for laboratory tests, continued abuse can be read from higher GGT values, increased AST/ALT ratio or an increased volume of red blood cells (MCV). In advanced liver cirrhosis, however, the values of hepatic enzymes fall short of sufficient sensitivity or specificity levels. More information about the actual abuse of alcohol can be derived from the percentage of carboxy-deficient transferrin estimation (%CDT) in serum or ethyl glucuronide in urine or hair[49]. A CDT value greater than 2.8% has a 79% sensitivity and 92% specificity for active alcohol abuse detection in patients with advanced cirrhosis[50].

PREVENTION OF ALD

Prevention of or treatment for alcohol abuse are crucial steps in the prevention of ALD[51]. Alcohol dependence is a chronic relapsing medical disorder which is treatable when efficacious medicines are added to enhance the effects of psychosocial treatment. Medication with, e.g., naltrexone and acamprosate showed mixed results in previous clinical trials[52]. Rősner *et al*[53] recently performed a meta-analysis to determine the efficacy and tolerability of acamprosate in comparison with placebo and other pharmacological agents. Almost 7000 patients in 24 double-blind randomised controlled trials were evaluated. Compared to placebo, acamprosate was shown to significantly reduce the risk of any drinking (RR 0.86) and to significantly increase the cumulative abstinence duration. The only side effect that was more frequently reported under acamprosate than with placebo was diarrhea. The authors of this Cochrane review conclude that acamprosate appears to be an effective and safe treatment strategy for supporting continuous abstinence after detoxification in alcohol dependent patients. Indeed, without a pharmacological adjunct to psychosocial therapy, the clinical outcome is poor, with up to 70% of patients resuming drinking within one year[54].

The prevention of liver injury in active alcohol abusers is not clinically applicable. For example, in an experiment, the addition to the diet of polyunsaturated fatty acids prevented alcohol-induced fatty liver and mitochon-

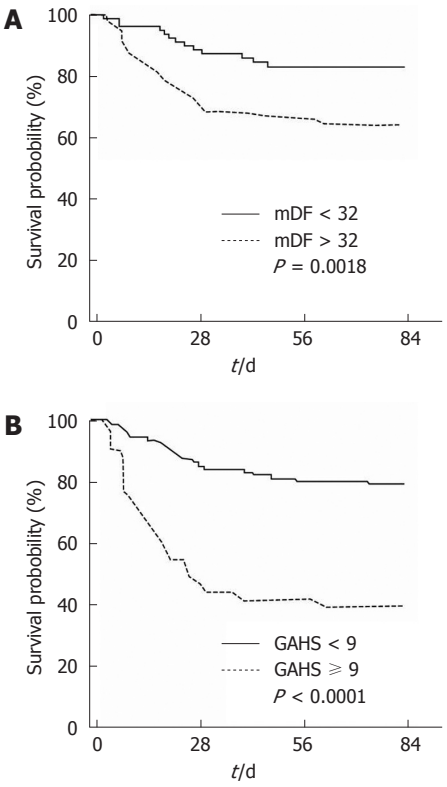

Figure 5 Kaplan-Meier survival analysis relative to the modified Maddrey discriminant function (mDF) (A) and the Glasgow alcoholic hepatitis score (GAHS) (B). The Glasgow score was developed on 241 patients and validated on 195 separate patients[44].

drial dysfunction in an animal model of ALD by protecting various mitochondrial enzymes, most likely through reducing oxidative/nitrosative stress[55]. The clinical use of similar medicaments would probably be always hampered by alcohol abusers´ failure to comply.

TREATMENT

Absolute abstinence is essential to consider any treatment for alcoholic liver disease. Even major changes, including cirrhotic restructuring, may show partial regression during total abstinence[56]. Portal hypertension declines and even regression of esophageal varices have been reported in abstainers. This, however, appears to have resulted from the remission of inflammatory changes and steatosis rather than from regressing fibrosis or cirrhosis. Sustained abstinence markedly improves the patient's prognosis in any phase of the liver disease[57], prevents the progression of the disease and fibrosis and, probably, also the development of hepatocellular carcinoma[58].

Pharmacotherapy of liver disease has but a supportive and rather dubious relevance. Treatment with silymarin, essential phospholipids or vitamin preparations was very popular in the past. Since an oxidative stress has been implicated in the pathophysiology of hepatic insult, the use of natural compounds with anti-oxidant properties represents an extremely popular therapeutic option for the treatment of liver disease. One such phytochemical, resveratrol, is remarkable as it is known as a major constituent of an alcoholic beverage, red wine. Resveratrol was shown to prevent liver injury by means of scavenging free radicals and inflammatory cytokines in experimental studies[59]. Its clinical utilization, though, is still far away. There are no conclusive data to prove the efficacy of any antioxidant medicaments for longer survival time or improved clinical conditions in the treatment of ALD. These are mostly cases of rather costly placebo. In contrast, dietary readjustment in the sense of sufficient energy intake and adequate supply of proteins is of value because malnutrition is a very poor prognostic factor in liver diseases[60]. What has been described as "liver diet" with increased supply of saccharides at the restriction of proteins and fats has no substantiation. Appropriate caloric intake with sufficient supply of proteins and polyunsaturated fats is important[34,61].

Severe alcoholic hepatitis has been treated with corticoids in many trials, with the best results in patients with hepatic encephalopathy, Maddrey score > 32 or Glasgow score > 9[62]. The Glasgow score is very simple to evaluate and its prognostic value is also greater than that of any other classification (Figure 5). The corticoid dose in that case is 40 mg prednisolone per day. The side effects of glucocorticosteroids must be also taken into consideration, as some patients on glucocorticosteroids experience adverse effects, mainly in the form hyperglycemia, Cushing's syndrome and increased risk of infection[63]. Despite the fact that the available trials are rather heterogeneous and some authors do not recommend the use of steroids in alcoholic hepatitis, recently published data emphasize the effect of corticosteroids on short-term survival of patients with severe alcoholic hepatitis[64], particularly in those with Maddrey score > 32.

Some trials and reviews of pentoxifylline (PTX) have shown a better risk/benefit profile than that of steroids and suggested that PTX could be a better first-line treatment in patients with severe AH. The efficacy of PTX in severe AH was first demonstrated by Akrividais *et al*[65] in 2000 on a group of 101 patients with severe AH. 24.5% of the patients who received PTX died during their index hospitalization, compared to a 46.1% mortality in the placebo group ($P = 0.037$). Remarkably, hepatorenal syndrome was the cause of death in 50% of patients on PTX compared to 91.7% of the HRS-related deaths in the placebo group ($P = 0.009$). According to the authors, the benefit appears to be related to a significant decrease in the risk of developing hepatorenal syndrome. In fact, renal dysfunction is frequent in patients with severe alcoholic hepatitis and, it seems, could be prevented with PTX[66].

Even in direct comparison with corticosteroids in a randomized trial, pentoxifylline was found to be superior to prednisolone for the management of severe alcoholic hepatitis regarding reduced mortality, improved risk-benefit profile and renoprotective effect[67]. Nevertheless, this observation should be confirmed on a larger cohort of patients[68]. A recent study by Lebrec *et al*[69] stopped short of confirming the effect of PTX on better survival but,

unlike a previous study, only Child-Pugh class C patients were included. However, the study did confirm a reduced risk of complications, such as bacterial infection, renal insufficiency, hepatic encephalopathy or gastrointestinal hemorrhage in patients treated with PTX compared to placebo.

Some centers recommend the use of PTX as the routine first line treatment of severe alcoholic hepatitis at a dose of 400 mg orally 3 times daily for a period of at least 4 wk[70]. They point to its safety, low cost and scope for long-term treatment. Significantly enough, the sweeping use of PTX as a first-line option is not generally recommended[71] and steroids should be used in patients with severe alcoholic hepatitis. Pentoxifylline could be used in patients with ineffectiveness or contraindications to steroids. The combination of pentoxifylline and steroids waits for clinical evaluation.

Biological treatment with anti- TNF-α antibodies fell short of expectations[72,73] so it can no longer be recommended for the management of alcoholic hepatitis[74].

Many studies with diverse conclusions have been published on the subject of nutrition and alcoholic hepatitis. In general, patients with alcoholic liver disease are frequently malnourished, a condition which worsens the prognosis[75]. However, the situation is not all that easy, as the spectrum of nutritional status in these patients may range from severe malnutrition to morbid obesity. The nutritional intervention on an outpatient basis depends on the degree of malnutrition, obesity and cooperation. In general, supplementation of multivitamins, folic acid and thiamine could be of value in chronic alcohol abuse, but data in the relevant literature are limited. Night-time nutritional supplements (approximately 700 kcal/d) may prevent muscle wasting and improve lean muscle mass in patients with liver cirrhosis[76] and should be considered, also relative to alcoholic hepatitis in patients with evidence of liver cirrhosis.

More data are available regarding the treatment of severe alcoholic hepatitis by enteral nutrition. The benefit of tube-feeding over the regular diet was demonstrated previously[77]. Patients on tube-fed nutrition had improved PSE scores, bilirubin and antipyrine clearance.

Many reviews and recommendations refer to a study by Cabre *et al*[78], which clearly demonstrated the efficacy of tube-fed nutrition. In their multi-center study, 71 patients with severe alcoholic hepatitis were randomized to receive 40 mg/d prednisolone or enteral tube feeding for 28 d and were followed up for 1 year. Mortality during the treatment was similar in both groups but during the follow-up significantly higher with steroids (37% *vs* 8%; $P = 0.04$), mainly because of infections with steroid treatment. The authors concluded that, unlike steroids, enteral nutrition had similar short-term mortality rates, improved 1 year mortality rates and reduced infectious complications. While some studies refrain from confirming any favorable effect of enteral feeding on survival, the implementation of tube-feeding in the treatment of acute alcoholic hepatitis is generally accepted[79]. There are only inconsistent data concerning the use of parenteral nutrition.

Despite the progress in the treatment of severe acute alcoholic hepatitis, the prognosis is still poor.

Alcoholic cirrhosis as such is treated in the same way as cirrhosis of other etiology; in particular, with adequate nutrition, bone disease prevention and prevention or treatment of liver cirrhosis complications (e.g., bleeding from esophageal varices, ascites, spontaneous bacterial peritonitis, hepatic encephalopathy)[80].

Quite a few medicinal products were tested for the treatment of alcoholic cirrhosis: antiphlogistics/propylthiuracil[81], colchicine[82], antioxidants/silymarin[83,84] and also phosphatidylcholine[85]. However, none of these were found to have a favorable effect on survival time and none are recommended for this particular indication any longer. Medicaments with a direct antifibrotic effect are still under evaluation[86].

Patients with advanced cirrhosis can be considered for liver transplantation, provided they are total abstainers[87]. In such cases, a five year post-transplantation survival can reach anything up to 85%[88].

CONCLUSION

Long-term intake of more than 30 g of absolute alcohol per day increases the risk of alcoholic liver disease; liver disease is nearly certain in long-term consumption in excess of 80 g of absolute alcohol per day. Alcoholic liver disease may take the chronic form (steatosis, steatohepatitis, fibrosis, cirrhosis) or that of acute hepatitis. Steatosis is fully reversible, which does not apply to the other conditions; cirrhosis is associated with a markedly shortened life expectancy. The results of laboratory testing in alcoholic liver disease usually include: increased GGT, AST/ALT ratio greater than 2 and increased MCV. Sonography will reveal enlarged liver and signs of steatosis. Absolute abstinence is an essential therapeutic precaution; no hepatoprotective treatment has been shown to improve the course of the disease. Likewise, there is no medicine that would demonstrably "protect" from the effects of alcohol.

The clinical course of severe alcoholic hepatitis could be improved with corticoids, enteral nutrition and pentoxifylline, although more clinical data are necessary to standardize or combine this treatment.

Patients with advanced cirrhosis should be considered for liver transplantation, provided they are verifiable abstainers.

Alcohol-Related Disease Impact (ARDI) application (http://www.cdc.gov/ARDI)

To assist professionals in state and local public health departments in estimating the impact of alcohol-attributable deaths (AAD) and years of potential life lost (YPLL)—a measure of premature death—the Centers for Disease Control and Prevention (CDC) funded the development of the Alcohol-Related Disease Impact (ARDI) application (http://www.cdc.gov/ARDI). Originally released in 1989, ARDI was specifically designed to allow states to calculate AAD, YPLL, direct health care costs, indirect morbidity and mortality costs, and non-health-sector costs associated with alcohol misuse.

In 2002, with support from a grant from the Robert Wood Johnson Foundation, the Alcohol Program in CDC's National Center for Chronic Disease Prevention and Health Promotion began updating ARDI and migrating it to the Internet to be more accessible to state-based epidemiologists and other users. In September 2004, the new version of ARDI was released in conjunction with a *Morbidity and Mortality Weekly Report* article entitled Alcohol-Attributable Deaths and Years of Potential Life Lost — United States, 2001 (http://www.cdc.gov/mmwr/preview/mmwrhtml/mm5337a2.htm). That report highlighted that approximately 75,000 AAD occurred in 2001 resulting in approximately 2.3 million YPLLs. In February 2008, additional years of data were added, which resulted in 5-year average annual estimates of health effects based on the years 2001–2005. This was done to produce more stable estimates than can be obtained from a single year of data. In December 2013, the data in ARDI were updated once again to provide average annual estimates of AAD (88,000) and YPLL (2.5 million) for 2006-2010.

ARDI includes reports for all 50 states with options to view each report by gender and age groups. Since the original release in 2004, ARDI has been enhanced to include reports specifically focused on individuals younger than 21 years of age. In addition, the custom data feature has been enhanced to make it easier for users to conduct sub-state (e.g., county-level) analyses of alcohol-attributable deaths and YPLL.

Alcohol Policy Information System (APIS) (http://www.alcoholpolicy.niaaa.nih.gov/)

Managed by the National Institute on Alcohol Abuse and Alcoholism (NIAAA), the Alcohol Policy Information System (http://www.alcoholpolicy.niaaa.nih.gov/) (APIS) provides detailed information on 35 state and federal alcohol policies in the policies. These policies fall under the following categories:

- Alcohol beverages pricing
- Alcohol control systems
- Blood alcohol concentration (BAC) limits
- Health care services and financing

- Pregnancy and alcohol
- Retail sales
- Taxation
- Transportation
- Underage drinking

APIS is intended to support alcohol policy research and public health practice in preventing excessive alcohol use. APIS also provides a variety of informational resources of interest to alcohol policy researchers, public health practitioners, community coalitions, and others involved with alcohol policy issues. The system is based on in-depth legal research conducted by attorneys with special expertise in alcohol policy. APIS is updated annually, and the list of policies being tracked by the system is updated periodically on the basis of researchers' and public health practitioners' needs.

Consumer Costs and Job Impacts from State Alcohol Tax Increases
(http://www.camy.org/action/taxes/taxtool/)

The Community Preventive Services Task Force recommends increasing alcohol taxes based on strong evidence that this can reduce excessive alcohol consumption and related harms. However, questions have been raised about the potential impact of alcohol tax increases on the cost of alcohol to individual drinkers and on state employment. To help answer these questions, the Alcohol Program in the Centers for Disease Control and Prevention (CDC) funded a research collaborative involving the Johns Hopkins Bloomberg School of Public Health, the University of Florida, the University of Illinois at Chicago, and Boston Medical Center. This new web tool was developed based on these research findings to model how much extra adult drinkers would pay for alcohol following various hypothetical state alcohol tax increases based on how much they drink, income, and employment status, as well as the effect these hypothetical tax increases would be expected to have on state employment.

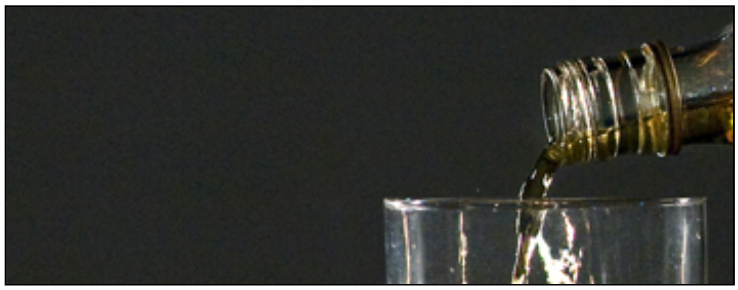
Excessive Drinking Costs U.S. $223.5 Billion



Excessive alcohol consumption cost the United States $223.5 billion in 2006, or about $1.90 per drink. By implementing effective community-based prevention strategies, we can reduce excessive alcohol consumption and its costs.

Excessive alcohol consumption is known to kill about 88,000 people in the United States each year, but a study released by the CDC and The Lewin Group shows that it has a huge impact on our wallets as well.

The cost of excessive alcohol consumption in the United States reached **$223.5 billion** in 2006 or about **$1.90 per drink**. Almost three-quarters of these costs were due to **binge drinking**. Binge drinking is defined as consuming four or more alcoholic beverages per occasion for women or five or more drinks per occasion for men, and is the most common form of excessive alcohol consumption in the United States.

The researchers found that the cost of excessive drinking was quite far-reaching, reflecting the effect this dangerous behavior has on many aspects of the drinker's life and on the lives of those around them. The costs largely resulted from losses in **workplace productivity** (72% of the total cost), **health care** expenses for problems caused by excessive drinking (11% of total), law enforcement and other **criminal justice** expenses related to excessive alcohol consumption (9% of total), and **motor vehicle crash** costs from impaired driving (6% of the total).

The study analyzed national data from multiple sources to estimate the costs due to excessive drinking in 2006, the most recent year for which data were available. The study did not consider a number of other costs such as those because of pain and suffering among either the excessive drinker or others that were affected by their drinking, and thus may be an underestimate. Nevertheless, the researchers estimated that excessive drinking cost **$746 for every man, woman, and child** in the United States in 2006.

What You Need to Know About Binge Drinking

- Binge drinking is reported by about 18% of U.S. adults.
- Binge drinking is most common among men, 18- to 34-year-olds, white people, and people with household incomes of $75,000 or more.
- Most binge drinkers are not alcohol dependent.

How Can We Prevent Excessive Alcohol Consumption and Reduce Its Economic Costs?

Communities can use evidence-based strategies, such as those recommended by the Community Preventive Services Task Force (http://www.thecommunityguide.org/alcohol) to prevent excessive drinking. These include:

- Increasing alcohol excise taxes.
- Reducing alcohol outlet density.
- Reducing the days and hours of alcohol sales.
- Holding alcohol retailers liable for injuries or damage done by their intoxicated or underage customers.

By implementing these evidence-based strategies, we can reduce excessive alcohol consumption and the many health and social costs related to it.

Licorice infusion: Chemical profile and effects on the activation and the cell cycle progression of human lymphocytes

José Cheel, Gabriela Onofre[1], Doris Vokurková[1], Lenka Tůmová, Jarmila Neugebauerová[2]

Department of Pharmacognosy, Faculty of Pharmacy, Charles University, Heyrovského 1203, 500 05 Hradec Králové, Czech Republic, [1]Institute of Clinical Immunology and Allergology, Charles University, Faculty of Medicine and University Hospital, Sokolská 581, 500 05 Hradec Králové, Czech Republic, [2]Mendel University in Brno, Faculty of Horticulture, Valtická 337, 69144 Lednice, Czech Republic

Submitted: 10-11-2009 Revised: 08-12-2009 Published: 13-02-2010

A licorice infusion (LI) and its major constituents were investigated for their capacity to stimulate the activation and the cell cycle progression of human lymphocytes, measured by the CD69 expression and DNA content, respectively. The chemical profile of LI was determined by high-performance liquid chromatography-diode array detection (HPLC-DAD). Results: Two major components of LI were identified as liquiritin (1) and glycyrrhizin (2); total flavones and flavonols were shown as its minor constituents. The LI (100-800 μg/ml) stimulated the expression of CD69 on lymphocytes in a concentration-independent manner. Values of the activation index (AI) of total lymphocytes treated with LI (100-800 μg/ml) did not differ significantly among them ($P < 0.05$), but were 50% lower than the AI value exhibited by cells treated with phytohemagglutinin (PHA). The LI showed a similar effect on T cells, but on a lower scale. Compounds 1 and 2 (12-100 μg/ml) did not stimulate the CD69 expression on lymphocytes. The LI, 1 and 2 showed no meaningful effect on cell cycle progression of lymphocytes. The experimental data indicates that LI stimulates the activation of lymphocytes as a result of a proliferation-independent process. This finding suggests that LI could be considered as a potential specific immune stimulator.

Key words: CD69 expression, flavonoids, HPLC, licorice, lymphocytes, phenolics

INTRODUCTION

Licorice, the dry roots of *Glycyrrhiza glabra* L. (Fabaceae), is considered one of the oldest and most widely used herbal drugs around the world, being present in most pharmacopoeias of Eastern and Western countries.[1] It has been traditionally used for respiratory, gastrointestinal, cardiovascular, genitourinary, eye, and skin disorders, and for its antiviral effects.[2] Glycyrrhizin and flavonoids such as liquiritin, isoliquiritin, and their aglycones have been reported as the major constituents of licorice and they are perceived as the active principles responsible for its pharmacological efficacy.[3]

The danger to global public health because of viral pandemic diseases such as those induced by influenza and HIV viruses requires the urgent evaluation of herbal drugs in widespread traditional use. Given that traditional sources mention licorice to treat symptoms attributable to viral infections, it is gaining attention as a potential immunomodulating agent.[4] The immunological action of herbs may involve the activation and induction of the cell cycle progression of immune cells, which play important roles in the generation of immune responses.[5] Licorice is consumed customarily in the form of teas and infusions,[6] but the immunomodulating properties of these aqueous preparations and the relation of such effect with its major constituents have been little explored.

The aim of the present study was to investigate the capacity of a licorice infusion (LI) and its major constituents to stimulate the activation and the cell cycle progression of human lymphocytes, using flow cytometry. The chemical profile of LI was determined by HPLC-DAD and spectrophotometric methods.

MATERIALS AND METHODS

Chemicals

Hide powder, standards (glycyrrhizin and quercetin), propidium iodide, ribonuclease A, phytohemagglutinin (PHA), and Tween-20 were obtained from Sigma Aldrich (Steinheim, Germany). Standard liquiritin was purchased

DOI: 10.4103/0973-1296.59963

from Wuhan Sunrise Technology Development Co., Ltd. (Hong Kong, China). Folin-Ciocalteu phenol reagent, aluminum chloride hexahydrate, gallic acid, and sodium carbonate were from Merck (Darmstadt, Germany). HPLC grade solvents were from Merck. Ultrapure water from the Milli-Q RG system (Millipore, Molsheim-France) was used. The monoclonal antibodies (phycoerythrin (PE), fluorescein isothiocyanate (FITC), and Allophycocyanin (APC) labeled) were obtained from Immunotech (France) and Dako (Denmark). X-Vivo medium was purchased from Bio-Wittaker (USA).

Sample collection and infusion preparation

Roots of *G. glabra* were collected in February 2008 from the Botanical Garden of the Faculty of Horticulture, Mendel University in Brno, Czech Republic (situated 164 m above sea level). The genetic resource was identified with the code 0001. The plant material was dried at 40°C in an oven and was subsequently ground to fine powders (mesh size 20). The infusion was prepared by adding 150 ml of distilled water (95-100°C) to a precisely weighed amount (1.50 g) of licorice powder.[7] The infusion was brewed for 20 minutes and was then filtered over Whatman No. 1 paper. The resulting aqueous extract was lyophilized and the extraction yield was calculated based on the dry weight of the licorice. The licorice lyophilized infusion (LI) obtained was assessed for its biological activities and chemical profile.

Determination of total content of phenolics

The total phenolic (TP) content was determined using the Folin-Ciocalteu procedure.[8] Briefly, the appropriate extract dilution was oxidized with the Folin-Ciocalteu reagent and the reaction was neutralized with sodium carbonate. The absorbance of the resulting blue color was measured at 760 nm after 30 minutes using a Shimadzu UV-1601 UV/Vis spectrophotometer. Quantification was plotted on a standard curve of gallic acid. The results were expressed as mg gallic acid equivalents (GAE)/100 mg of LI. Data are reported as means ± standard deviation (SD) to an accuracy of three replicates.

Determination of total content of tannins

After removal of tannins by adsorption on an insoluble matrix (hide powder), the total tannin (TT) content was determined by Folin-Ciocalteu procedure explained briefly in the previous paragraph. Calculated values were subtracted from the total phenolic contents and total tannin contents are expressed as mg gallic acid equivalents (GAE)/100 mg of LI. Data are reported as means ± standard deviation (SD) to an accuracy of three replicates.[9]

Determination of total content of flavones and flavonols

The total flavones and flavonols (TF) content was determined according to the aluminum chloride method.[8] Quercetin was used as a reference for the calibration curve. The absorbance of the reaction mixture was measured at 415 nm. Results were expressed as mg quercetin equivalents (QE)/100 mg of LI. Data are reported as means ± SD to an accuracy of three replicates.

HPLC-diode array detector analysis

The HPLC analysis was performed with a Jasco PU-2089 pump equipped with a Jasco MD-2015 diode array detector (DAD), and chromatographic separations were performed on a LiChrospher RP-18 column (4.0 × 250 mm i.d., 5 μm). Isocratic elution was used with a mobile phase containing acetonitrile: Methanol: Water: Glacial acetic acid (35:35:29:1, by volume) at a flow rate of 1 ml/min.[10] Separations were carried out at 25°C with an injection loop of 20 μl. The DAD detector was operated in the range of 200-650 nm, and the analysis was performed at 254 nm. Components of LI were identified by comparing their retention times and UV spectra with those of authentic standards (liquiritin and glycyrrhizin) under identical analysis conditions. Solutions at different concentrations of each standard were injected into the HPLC to check the linearity between concentration and peak areas, and a response factor was calculated. Quantifications of liquiritin and glycyrrhizin were done using these calibration factors.

Activation of immune cells

The activation of total lymphocytes and T cells was analyzed by flow cytometry, measured by CD69 expression.[11] Using sterile 96-well flat-bottomed plates, 100 μl of peripheral blood suspension were incubated along with 100 μl of X-Vivo medium containing test samples with increasing concentrations and without test samples (control). The mitogen PHA was used as a positive control at 10 μg/ml. Samples were filtered through 0.2 μm filters before use. Final concentrations of LI and compounds in the assay media were in the range of 100-800 μg/ml and 12-100 μg/ml, respectively. Plates were then incubated at 37°C with 5% CO_2 for 24 hours. After incubation, 40 μl of each incubated suspension was labeled with a cocktail of fluorescently labeled antibodies CD69 PE, CD69 FITC, CD3 APC. Flow cytometric analysis was performed on a Cytomics FC500 flow cytometer (Beckman Coulter, USA) and data were analyzed by CXP analysis software (Coulter Electronic, USA). Cell activation was measured by increases in mean fluorescence intensities (MFI) because of the expression of CD69 on the cell surface. Fluorescence signals were obtained as logarithmically amplified signals. Values of activation are presented as activation index (AI), which were calculated by dividing the MFI of treated cells with test samples by that of untreated cells (control). A positive immune cell response was defined as an AI ≥ 2. Data were presented as the mean ± SD for three experiments.

Cell cycle progression of lymphocytes

To assess the effect of samples on the cell cycle progression of lymphocytes, the DNA content of individual cells stained with propidium iodide was analyzed by flow cytometry.[5] Briefly, 100 µl of diluted peripheral blood (1:10) was incubated with test samples for 72 hours. Lymphocytes were isolated from red cells by lysis in hypotonic solution followed by centrifugation. Cells were fixed with 4% paraformaldehyde for at least five minutes and the supernatant was removed by centrifugation at 1100 rpm for 10 min. A volume of 500 µl of 0.5% Tween, 50 µl of ribonuclease A, and 50 µl of propidium iodide solution were added and the mixture was incubated for 60 minutes at 37°C with 5% CO_2. Fluorescence (DNA content) was measured on a Cytomics FC500 flow cytometer (Beckman Coulter, USA). A minimum of 10 000 cells analyzed in each sample served to determine the percentages of cells in each phase of the cell cycle; Multicycle AV software was used for the analysis (Phoenix Flow Systems Inc., USA).

Statistical analysis

Data were analyzed by one-way analysis of variance (ANOVA) followed by Tukey's multiple comparison test using the GraphPad Prism 5 software. Differences were considered significant when $P < 0.05$.

RESULTS

The present study reports the total content of phenolic, flavonoids, and tannins in a licorice infusion [Table 1]. The extraction yield of licorice lyophilized infusion (LI) was about 30%. The data from the HPLC-DAD analysis of LI is presented in Table 1, whereas, the HPLC chromatogram is presented in Figure 1. The two major components of LI were identified as liquiritin 1 and glycyrrhizin 2 [Figure 2] by comparing with the retention times and UV spectra of authentic standards. Peaks 3 and 4 of the chromatogram [Figure 1] showing UV λmax at 248 nm were preliminarily identified as derivatives of glycyrrhetic acid.

The effects of LI, 1, and 2 on the activation of total lymphocytes, measured by the CD69 expression, was analyzed by flow cytometry. As indicated by a shift to the right in histograms [Figure 3b, 4b], the CD69 expression on cells was increased after 24 hours. As the cells were activated, the amount of the fluorescently labeled antibodies bound to them increased. The LI moderately stimulated the expression of CD69 on lymphocytes in a concentration-independent manner in the range of 100-800 µg/ml. Values of the activation index (AI) of total lymphocytes treated with LI in the range of 100-800 µg/ml did not differ significantly among them ($P < 0.05$), but were lower than the AI value exhibited by cells treated with PHA [Figure 3d]. The LI showed a similar effect on T cells, but on a lower scale [Figure 4d]. Compounds 1 and 2 in the range of 12-100 µg/ml did not stimulate the CD69 expression on lymphocytes [Figure 3c, 4c]. It was observed that the LI, 1, and 2 showed no meaningful effect on cell cycle progression of lymphocytes. Most of the lymphocytes treated with LI, 1, and 2 were in G_1 phase, and there was only a very small number of cells in S or G_2 phases. The PHA stimulated lymphocytes to enter into the S and G_2 phases after 72 hours of culture [Figure 5].

DISCUSSION

Chemical analysis

About 300 kinds of phenolic compounds have been isolated from various species of *Glycyrrhiza* and many of them are described as exhibiting biological actions that supplement the efficacy of licorice.[3] Polyphenols are bioactive compounds believed to be involved in the defence process against oxidative damage in biological systems, owing at least in part to their antioxidant properties.[12] In a prior study, the content of TP (7.42 µg/mg) and TF (0.88 µg/mg) in a licorice extract were reported.[13] In another study, the TF content of *G. pallidiflora* was measured by two different methods. The TF contents were 2.09 mg/100 mg and 4.27 mg/100 mg of the extract, measured by the $AlCl_3$ and $Al(NO_3)_3$ methods, respectively.[14] Most reports on the flavonoid content in licorice are usually based on flavanones and chalcone such as liquiritin, isoliquiritin, and their corresponding aglycones.[3] Unlike flavanones from licorice, other types of minor flavonoids such as flavones and flavonols have been shown to exhibit strong antioxidant effects.[15] To date, there is very limited information on the TT content in the roots of

Table 1: Content of liquiritin, glycyrrhizin, and total polyphenolics in licorice infusion

Compounds	Content in dried roots	Content in lyophilized extract (LI)	Regression equation	Correlation coefficient (r^2)
Liquiritin	1.55 ± 0.05	5.18 ± 0.17	$Y = 246.02X + 1.9512$	0.9999
Glycyrrhizin	2.23 ± 0.04	7.43 ± 0.16	$Y = 161.05X + 0.0747$	0.9995
TP content[a]	1.75 ± 0.02	5.83 ± 0.06	$Y = 0.1011X + 0.0206$	0.9992

[a]Total phenolics (TP) and[c]total tannins (TT) contents are expressed as mg gallic acid equivalents (GAE)/100 mg LI.[b]Total flavones and flavonols (TF) content is expressed as mg quercetin equivalents (QE)/100 mg LI. Contents of liquiritin and glycyrrhizin are expressed as percentage (w/w) in terms of dry weight. Each value represents mean (n = 3) ± SD

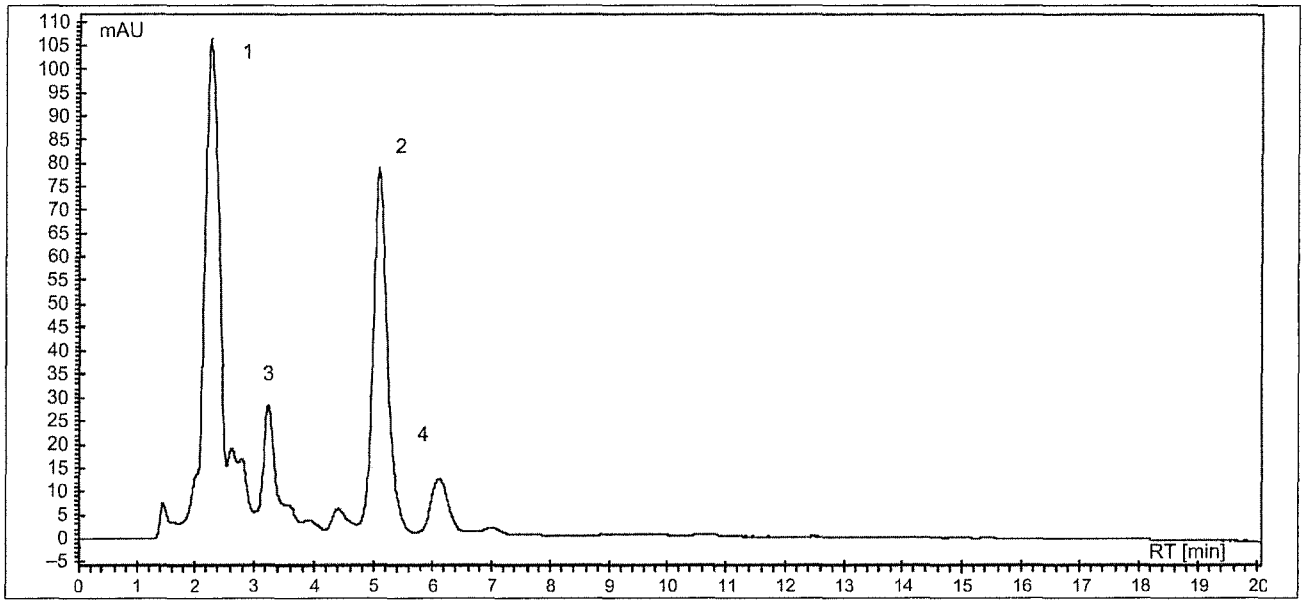

Figure 1: HPLC chemical profile of licorice infusion (LI). Detection at 254 nm. Peaks: (1) liquiritin; (2) glycyrrhizin; (3) and (4) glycyrrhetic acid derivatives (at column width)

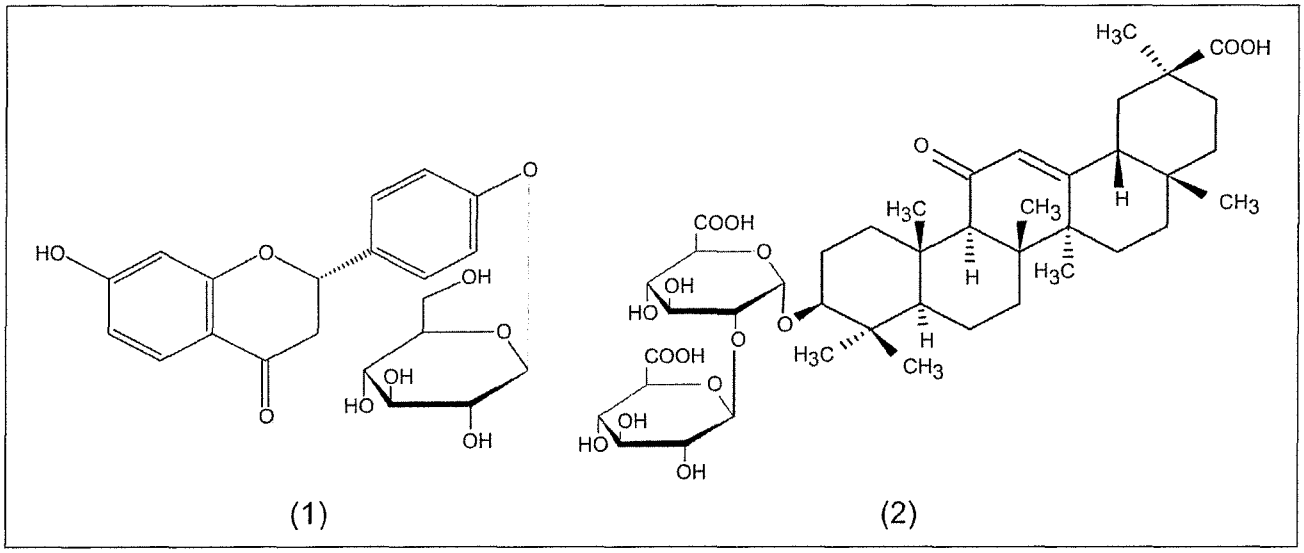

Figure 2: Structures of liquiritin (1) and glycyrrhizin (2) (at column width)

Glycyrrhiza species. Two flavonoids, named licochalcone B and glycyrrhisoflavone, were isolated from an acetonic- aqueous extract of licorice and they exhibited tannin-like activity.[15] Glycyrrhizin has been reported to constitute 10-25% of licorice extract[16] and the liquiritigenin glycosides were reported to constitute 1.6% of licorice aqueous extract.[17] As can be noticed, the comparison between the values reported by different laboratories can be complicated because of substantial differences in sample preparation, geographic sources, harvesting, and expression of results.

Activation of immune cells

The CD69 glycoprotein is a very early cell activation molecule expressed on the surface of T, B, and Natural Killer (NK) cells following activation.[18] It can appear within 1-2 hours of activation and exhibits maximal expression levels between 18 and 24 hours after stimulation.[19] Although a physiological ligand for CD69 has not yet been identified, its wide distribution and the observation that crosslinking of the molecule generates intracellular signals suggest a significant role for CD69 in immune response.[20] Three major types of lymphocytes include T, B, and NK cells. Adaptive immune responses are based on the activities of T lymphocytes (also called T cells) and B lymphocytes (B cells). The key to the adaptive immune system is the presence of the extremely variable

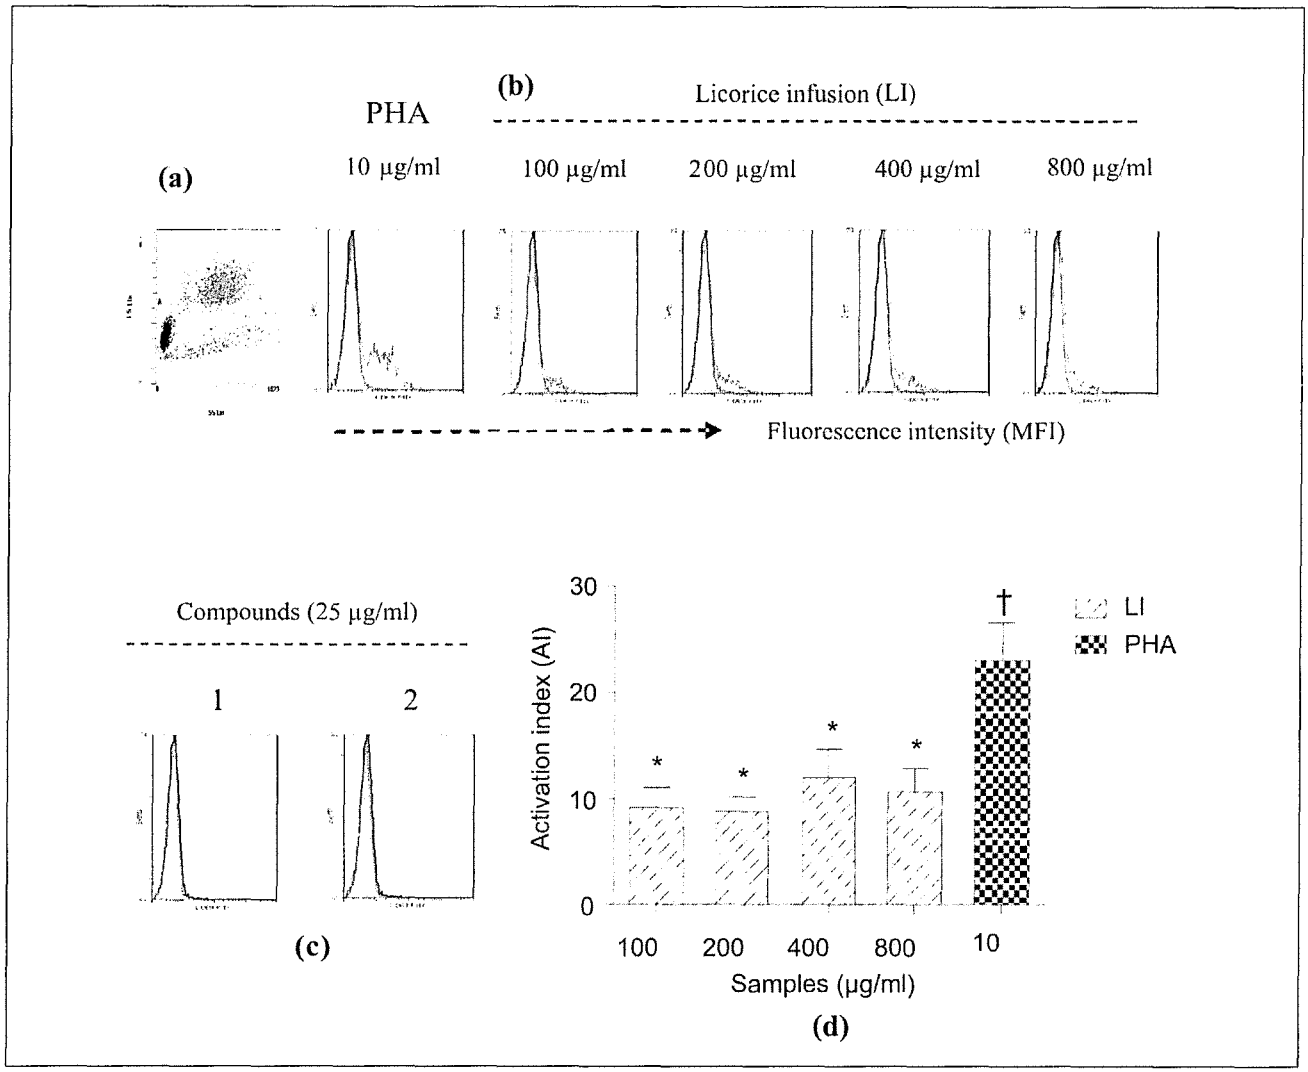

Figure 3: Effect of licorice infusion (LI), liquiritin (1) and glycyrrhizin (2) on activation of total lymphocytes, as measured by CD69 expression. Lymphocytes were initially gated by their characteristic forward (FSC) and side scatter (SSC) profiles, which represent size and granularity, respectively. The activated lymphocytes in circular gate A (a) were then analyzed for fluorescent intensity. The filled histograms represent the group control (untreated) and the open histograms the stimulated (treated) group (b). Compounds 1 and 2 (at range of 12-100 µg/ml) were inactive and histograms (c) are shown as representative figures. (at page width); Bar graphic (d) shows the effect of LI on the total lymphocytes as activation index (AI)

antigen-specific receptors of the T lymphocytes (called TCRs) and B lymphocytes (called B-cell receptors [BCRs], immunoglobulins, or antibodies). NK cells are part of the lymphoid lineage but are distinct from T and B lymphocytes because they do not express the specialized receptors associated with the adaptive immune response. Instead they have two other types of receptors that determine their ability to identify and kill targeted host cells: Killer activation receptors and killer inhibition receptors. NK cells are important elements in innate defenses against virally infected and cancerous host cells.[21]

As can be deducted from AI values [Figure 3d, 4d], the activation of total lymphocytes and T cells by LI represents about 50 and 34% of those promoted by PHA, respectively. In addition, by comparing the AI of total lymphocytes with those of T cells, it was observed that about 50% of the activation of total lymphocytes could proceed from the T cells activation. Although the effect of LI on the CD69 expression was moderate, this fact could be hypothetically interpreted as beneficial, given that increased level of CD69 expression on T cells has been associated with some autoimmune diseases.[22,24] Licorice has multiple constituents and not one active ingredient; therefore, it is possible that they are able to act in a regulatory way, both activating and modulating the immune response. It is also questionable whether the LI immunostimulating effect is long-term because the CD69 expression on the surface

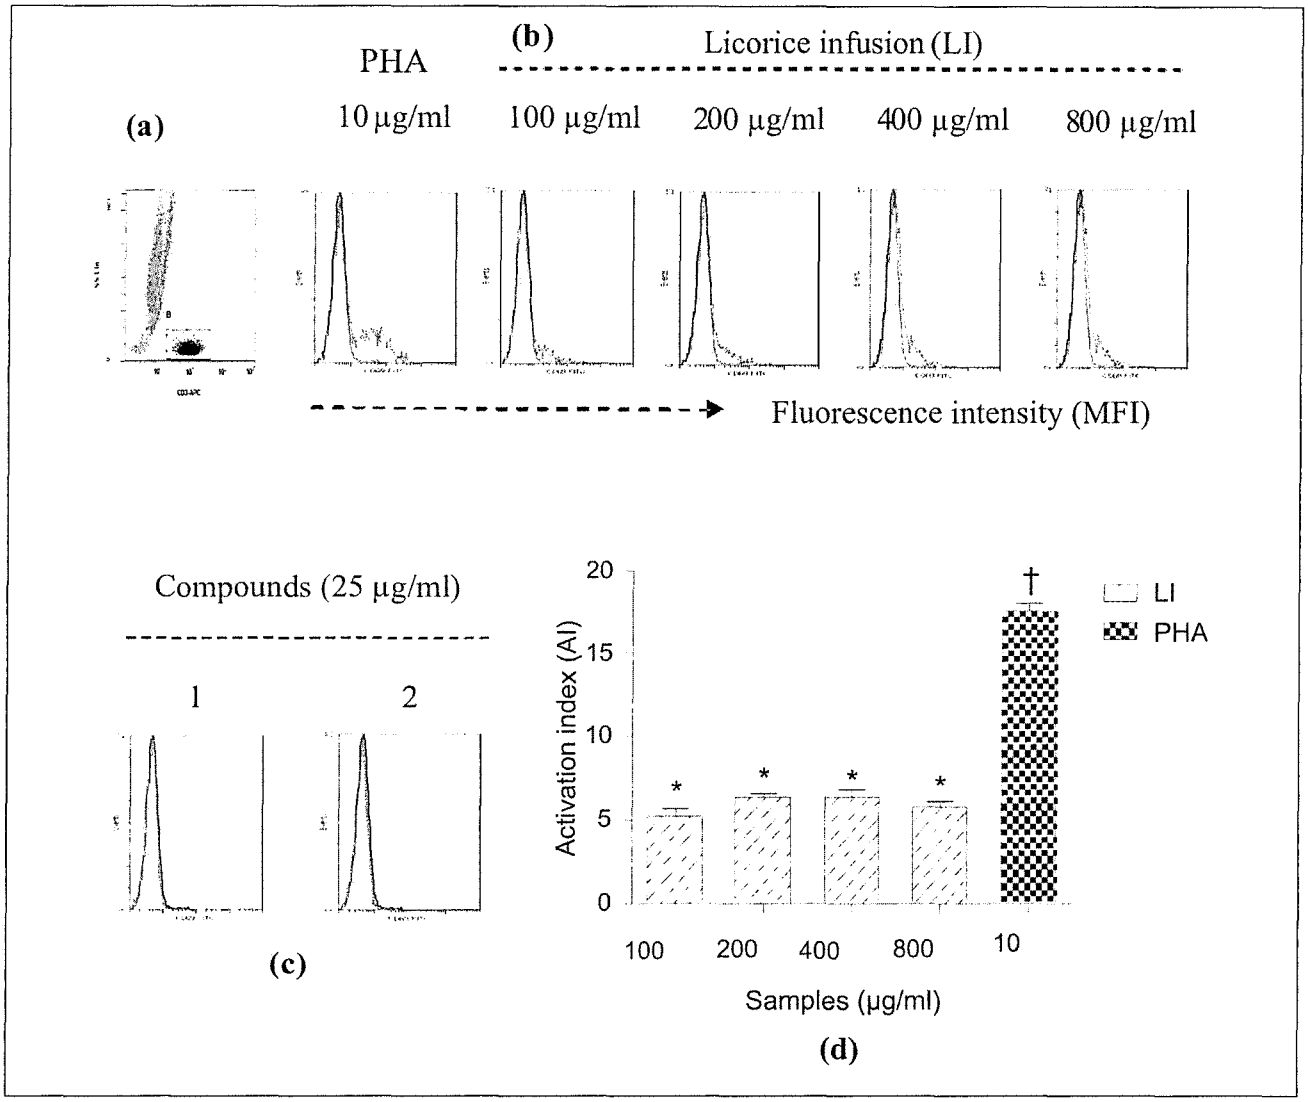

Figure 4: Effect of licorice infusion (LI), liquiritin (1) and glycyrrhizin (2) on activation of T lymphocytes, measured by CD69 expression. For visualization of T lymphocyte subset, the surface immunostaining with anti-human CD3 was used. The activated cells in rectangular gate B (a) were then analyzed for fluorescent intensity. The filled histograms represent the group control (untreated) and the open histograms the stimulated (treated) group (b). Compounds 1 and 2 (at range of 12-100 µg/ml) were inactive and histograms (c) are shown as representative figures. (at page width); Bar graphic (d) shows the effect of LI on the T lymphocytes as activation index (AI)

of immune cells not only occurs very rapidly, but also declines rapidly (disappearing after two days). Therefore, this study measured the CD25 expression, a later-expressed activation marker, but the expression was very low (data are not shown). Apparently, regular consumption of licorice infusion would be important for its long-term effect.

Recently, tinctures of *Echinacea purpurea*, *Astragalus membranaceus*, and *G. glabra* were shown to stimulate T cells, determined by CD69 expression. These three herbs had an additive effect on CD69 expression when used in combination and no chemical compound was related with the effects observed.[11] In contrast, previous *in vitro* studies revealed antiviral activity of glycyrrhizin against HIV-1, SARS related coronavirus, respiratory syncytial virus, arboviruses, vaccinia virus, and vesicular stomatitis virus. Mechanisms for antiviral activity included the reduced transport to the membrane and sialylation of viral surface antigen, reduction of membrane fluidity leading to inhibition of fusion of the viral membrane with the cell, induction of interferon gamma in *t*-cells, inhibition of phosphorylating enzymes in vesicular stomatitis virus infection, and reduction of viral latency.[4]

Licorice is popularly consumed in the form of teas and infusions;[6] however, studies on the immunomodulating effects of licorice by measuring the CD69 expression have been focused mainly on its tincture.[11] Infusion and tincture

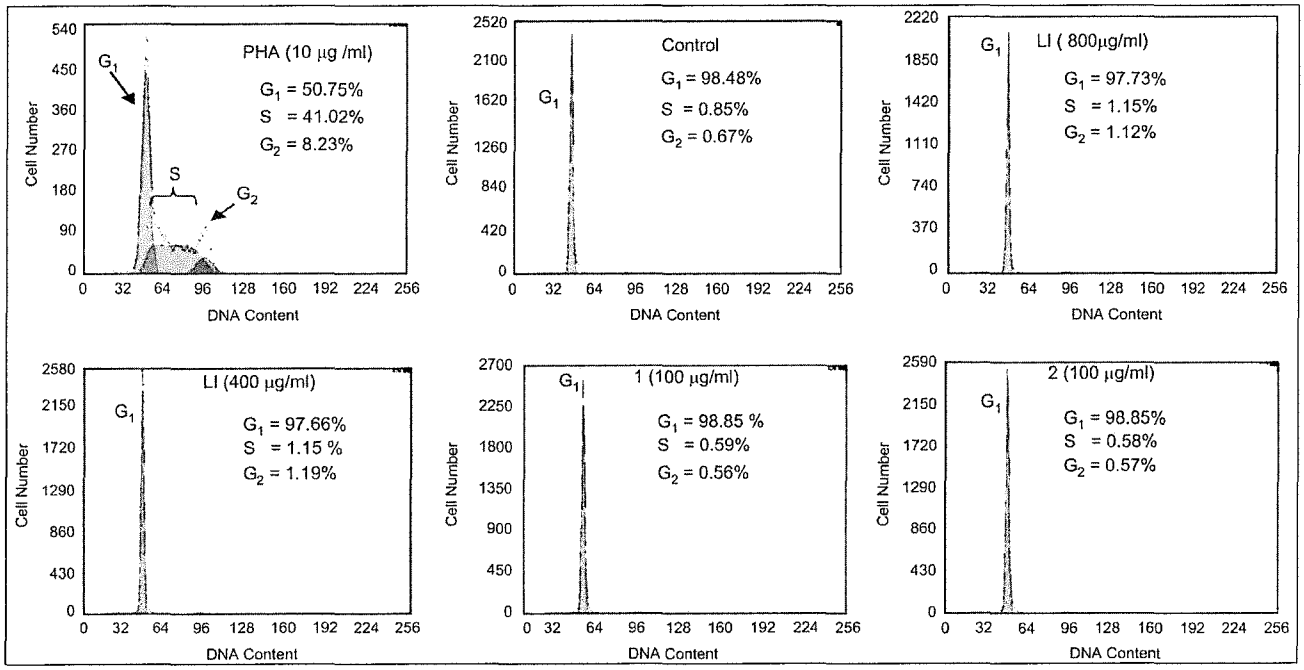

Figure 5: Effects of licorice infusion (LI), liquiritin (1) and glycyrrhizin (2) on the cell cycle progression of human lymphocytes. The LI, 1, and 2 showed no meaningful effect on cell cycle progression of lymphocytes. One representative experiment is shown and the percentages of cells in each phase of the cell cycle (G_1, S, and G_2 phases) are shown. (at column width)

of licorice have different chemical profiles[23,25] and therefore are expected to show different bioactivities. In the present study, the effect of a LI on the activation of lymphocytes was investigated for the first time. In contrast to a number of prior investigations,[26] the current study indicates that glycyrrhizin does not seem to be involved in the immunostimulating effect of LI, as measured by the CD69 expression.

Cell cycle progression of lymphocytes

The immunomodulating action of herbs may involve not only cell activation, but also cell proliferation. It is described that the interaction of lymphocytes with antigens or PHA initiates a cascade of biochemical events and gene expression, which induces the resting immune cells to enter the cell cycle, and then begin proliferating and differentiating.[27] By measuring the incorporation of propidium iodide in lymphocyte DNA using flow citometry, it was observed that LI, 1, and 2 had no effect on the cell cycle progression of lymphocytes. It has been suggested in different systems that CD69 expression may precede cell proliferation, maturation or differentiation.[28] Nevertheless, the CD69 expression may not completely overlap with cells that undergo DNA synthesis following antigen receptor engagement. Although the immunologic consequences of lymphocyte clonal expansion are well established and critical to the development of immunity, the relevance of CD69 expression to this process is less understood.[29] The emerging data from the present study suggests that the LI-activated lymphocytes express CD69 as a result of a proliferation-independent process. In the current investigation, the stimulating effect of LI and its two major constituents on the cell cycle progression of lymphocytes was investigated for the first time.

CONCLUSION

The present *in vitro* study demonstrates that licorice infusion (LI) stimulates the activation of lymphocytes, mainly T cells. The two major components of LI were identified as liquiritin (1) and glycyrrhizin (2) and they seem not to be involved in the activation of lymphocytes. Flavones and flavonols were identified as minor constituents of LI. This report establishes the need for future studies to determine the *in vivo* effect of LI on lymphocytes and to identify its active constituentes. This herbal preparation might be a potential alternative for mounting an effective immune response and as a preventive barrier against both viral and bacterial infections, and during immunosenescence.

Clinical Analysis for Magnesium Isoglycyrrhizinate in the Treatment of Chronic Hepatitis

CHEN Dan-dan,GONG Zuo-jiong (Renmin Hospital of Wuhan University,Wuhan Hubei 430060,China)

Objective To observe the efficacy of magnesium isoglycyrrhizinate in the treatment of chronic hepatitis. Methods 72 patients with chronic hepatitis B were randomly divided into treatment group and control group.The 36 hepatitis sufferers were treated with 100mg magnesium isoglycyrrhizinate added into 250ml 10%glucose injection liquid,and the other 36 sufferers control group were treated with compound Glyeyrrhizin 150mg added into 250ml 10%glucose injection liquid,I.V.drip,once a day for 1 month.When the treatment was over,the practical effects were analyzed. Results The levels of ALT,AST and TBIL dropped more rapidly than those in control group and there was significant difference in symptom improvement between treatment group and control group(P0.05). Conclusion Clinic symptom and liver function index can be improved after treatment with magnesium isoglycyrrhizinate injection in chronic hepatitis sufferers,and there are few side reactions happened.

Evaluation of oxidative stress at different time intervals after single dose of alcohol with or without NTX in rats (CTPL/ROS/01/2015)

Objective

The primary objective of the present study is to evaluate extent of oxidative stress at different time points after single dose of alcohol with or without NTX on selected parameters.

Table 1: Animal study groups

Groups	Dose of alcohol	NTX %
1. Alcohol	1 g/kg, p.o., bolus	-
2. NTX + Alcohol	1 g/kg, p.o., bolus	1.4

Brief Schematic Experimental Study Protocol:

Laboratory acclimatized animal (rat, n=16 in each group)

↓

Single Alcohol (1 gm/kg)/NTX+ alcohol (1 gm/kg) were administered orally

↓

Blood samples were collected at 0 min (pre dose), 30 min, 60 min, 120 min and 240 min post dose. Serum samples were separated and stored at -20 °C in aliquots.

↓

Following parameters were tested from serum samples:

1. Reactive oxygen species (ROS) using a) ROS ELISA kit and b) spectrophotometric assay of ROS metabolites (d-ROM test)
2. Serum MDA by ELISA method
3. Serum protein carbonyl content by ELISA method
4. Serum total GSH and GSSG
5. Total WBC count

Results:

Table 2: Changes in serum ROS level (U/ml) at different time points after single oral dose of alcohol (1 gm/kg bw) with or without NTX

Time points (hours)	**Alcohol** (1 gm/kg bw)	**SE**	**Alcohol + NTX** (1 gm/kg bw)	**SE**

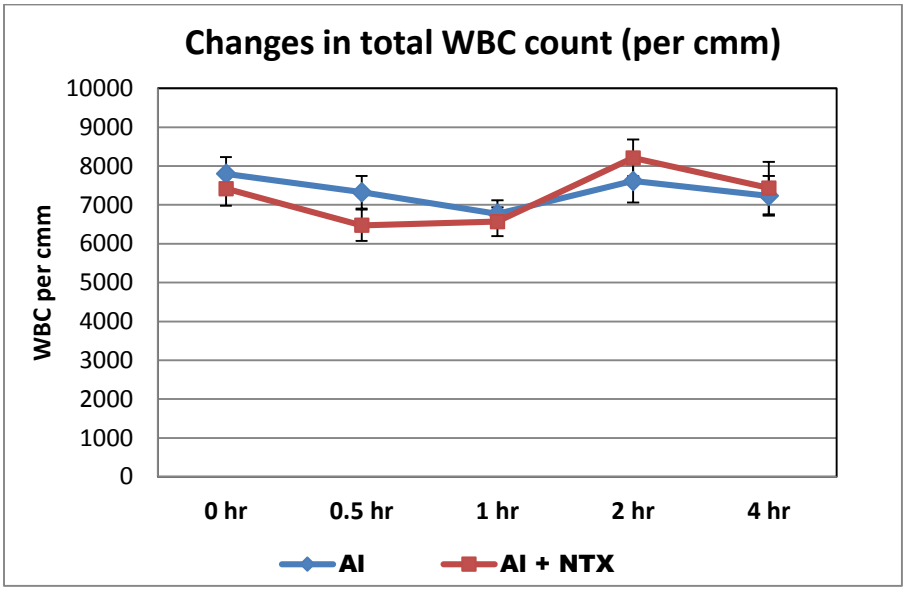
Table 8: Changes in total WBC count (per cmm) at different time points after single oral dose of alcohol (1 gm/kg bw) with or without NTX

Time points (hours)	Alcohol (1 gm/kg bw)	SE	Alcohol + NTX (1 gm/kg bw)	SE
0	7800	427	7417	437
0.5	7325	420	6475	402
1	6770	347	6567	373
2	7617	558	8208	473
4.00	7233	508	7433	677



Conclusions:

1. Orally administered alcohol at a dose of 1 gm/kg/bolus showed transient rise in ROS and ROS metabolites levels. Alcohol containing NTX (1.4%) showed slightly lower ROS generation both in terms of direct ROS and ROS metabolites. The comparison between AUC values of alcohol with or without NTX showed that NTX could dampen the serum ROS level by around 6%.

2. Single oral dose of alcohol (1 gm/kg/bolus) showed a rise in serum MDA level around 1 hour after administration. Animals received alcohol+ NTX did not show such peak. In terms of AUC values, NTX showed 6.7% less MDA value, compared to only alcohol group.

3. Similarly, addition of NTX prevents slight fall of serum total GSH level after alcohol administration and maintains total GSH level. In terms of AUC values, NTX showed nearly 12% more total GSH values compared to only alcohol.

4. Protein carbonyl, total WBC showed very similar trends in both the groups.

Evaluation of reactive oxygen species (ROS) from blood at different time intervals after oral consumption of two different alcohol formulations: A comparative, double blind, crossover, pilot clinical trial

Introduction

Exposure to acute or chronic alcohol triggers production of reactive oxygen species (ROS) with concomitant drop in the level or activity of antioxidants. The resulting state, which is characterized by a disturbance in the balance between ROS production, on one hand and ROS removal and repair of damaged complex molecules, on the other results in a comprehensive oxidative stress condition.

The major pathways of alcohol metabolism responsible for the generation of ROS are alcohol dehydrogenase in the cytosol, microsomal ethanol oxidizing system in the endoplasmic reticulum and aldehyde oxidase in the mitochondria (Lieber CS, 1997, Mira L et al., 1995). It has been comprehensively demonstrated that ROS accumulation contributes to alcohol-induced syndrome including liver injury (Reinke LE, 1985). The interaction of ROS with bio-molecules leads to alcohol induced toxicity includes enhanced lipid peroxidation, protein carbonyl formation, decreases in hepatic antioxidant defense especially GSH (Knecht et al., 1990) (Tsukamoto and Lu, 2001).

Objective of the study

The primary objective of the study will be to evaluate levels of ROS and other related oxidative stress markers from blood after oral consumption of two different alcohol formulations.

Inclusion criteria

- Male healthy participants (volunteers, who are regular/frequent/social alcohol drinkers)
- Aged between 25-50 years
- Body weight range of 55-85 kg

Exclusion criteria

- Volunteers with acid peptic disorder, diabetes mellitus, gallstones, neurological and psychiatric disorders, history of drug abuse.
- Volunteers consuming certain concomitant medications like antibiotics, antidepressants, antihistamines, anticonvulsants, cardiovascular medications, sedatives and hypnotic.

Study procedure:

- All subjects were asked to maintain their normal life style and were advised not to have excess food, cold drinks, coffee and avoid heavy physical exercise during the study period.

- The alcohol was provided in separate bottle and the amount was adjusted so that the alcohol intake would be around 1.5 gm/kg, bw (around 225-350 ml vodka). The subjects were allowed to drink with some diluents (limca, sprite, coke, water) with some snacks within a period of 1.0 hours.
- Blood will be collected at following intervals:
    - Before drinking initiated (mentioned as: -1 hr)
    - Just after the completion of drinking (mentioned as 0 min)
    - 30 min after the completion of drinking
    - 60 min after the completion of drinking
    - 120 min after the completion of drinking and
    - 240 min after the completion of drinking
- The study has been conducted in day time (between 10.00 a.m. to 6.00 p.m.)
- The subjects were allowed to have a light lunch after collection of 2 hours blood.

Statistical analysis

Percentage changes for measures were calculated from the difference between means of the each time points of alcohol and NTX groups (viz., 1 hr alcohol vs 1 hr NTX). Paired 'student's t-test' was carried out between the values of each time points of two groups (alcohol and NTX) and $p < 0.05$ was considered statistically significant.

Results:

Table 1: Demographic pattern of participants:

Parameters		
No. of completed subjects in each arm	12	
Age (Year)	33.83 ± 9.12	
Body weight (Kg)	65.42 ± 17.89	
Height (cm)	1.66 ± 0.06	
BMI	23.36 ± 4.56	
Al-consumed (both groups) (ml)	240.67 ± 49.13	
Gm/kg body wt	1.49 ± 0.12	
	Alcohol	NTX
Sys-BP (mm Hg)	119.17 ± 14.28	120 ± 10.44
Dia-BP (mm Hg)	77.17 ± 4.61	78.25 ± 3.74
Pulse rate (beats/min)	73.08 ± 8.08	72.42 ± 6.57
Drinking time (min)	47.08 ± 11.77	49.17 ± 12.40

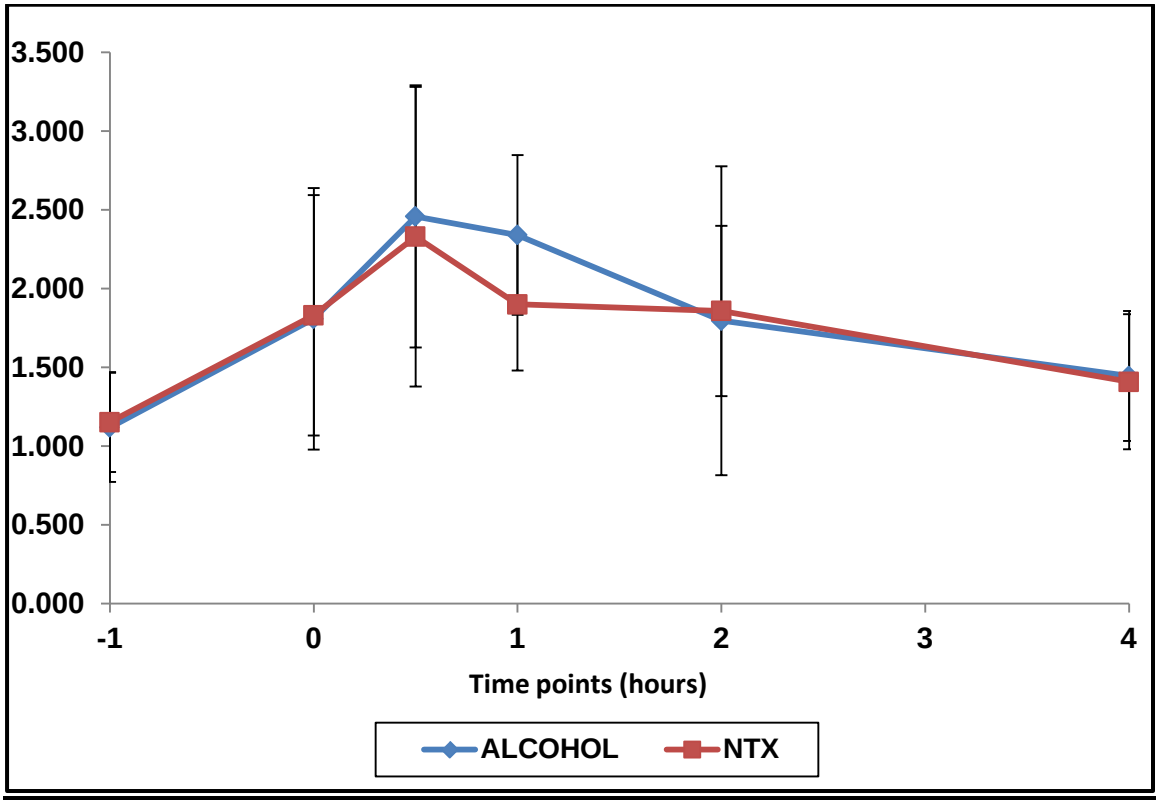

Fig.5: Changes in serum PC levels at different time intervals after alcohol consumption.

Conclusions:

1. Consumption of alcohol at a dose of around 1.5 gm/kg within a period of 40-60 minutes showed transient rise in ROS and ROS metabolites (dROM) levels. Alcohol containing NTX showed slightly lower ROS generation both in terms of direct ROS and ROS metabolites. A significant ($p<0.05$) drop in ROS levels were observed at 1 and 4 hour (20.09% and 14.67% respectively). Levels of ROS metabolites (as judged by dROM test) also significantly ($p<0.05$) decreased at +0 and 2 hour (11.94% and 11.34% respectively) indicating that NTX could dampen the serum ROS level.
2. Initial loss of serum total GSH level was slightly better managed by NTX group (+6.5%) though that was not statistically significant. However, NTX could able to maintain a significantly ($p<0.05$) higher level of serum total GSH during 30 minutes and 1 hour period (10.83% and 11.91% respectively). Whereas only alcohol group showed slow recovery of serum GSH level.

3. Throughout the study period, the increase in serum MDA level was found to be less pronounced in NTX group, particularly 30 minute and 4 hour time points (-12.27% and -11.03% respectively; $p<0.05$).

4. Serum protein carbonyl level showed initial transient rise in both the groups. However, serum level of PC in NTX group was significantly reduced at 1 hour (-18.81%, $p=0.051$) compared to only alcohol group at same time point. However, serum PC levels of both the groups slowly coming down to near baseline value at the end of 4 hours.

5. The present pilot study indicates the probable contribution of NTX in reducing ROS level in alcohol drinkers which could be effective in reducing alcohol induced diseases in long run.

(57) **ABSTRACT**

The present invention relates to reduced toxicity of functional alcoholic beverage composition comprising distilled alcohol, deionized water, 18β-Glycyrrhizin or 18α-Glycyrrhizin and a sugar alcohol or sugars, having pH in the range of 4.0-9.0. More particularly, alcoholic beverage composition comprises distilled alcohol, deionized water, 18β-Glycyrrhizin or 18α-Glycyrrhizin and a sugar alcohol/sugars as hepato-protectants. The present invention provides an alcoholic beverage for reducing hepatotoxicity caused by its consumption and a process to manufacture the said alcoholic beverage.

REDUCED TOXICITY IN ALCOHOLIC BEVERAGES

The following specification particularly describes the invention and the manner in which it is to be performed.

FIELD OF INVENTION

The present disclosure provides an alcoholic beverage having reduced hepato-toxicity. The invention also relates to a process for the preparation of the said beverage.

BACKGROUND OF THE INVENTION

Ethanol consumption could lead to 60 medical conditions. Acute as well as chronic toxic effect of ethanol may ensue in irreversible organ damage (Das S. K. et. al., Indian journal of Biochemistry & Biophysics, 2010, Vol. 47, 32). The widely accepted forms of alcoholic liver diseases (ALD) are simple fatty liver (steatosis), which is reversible with abstinence, fatty liver accompanied by inflammation (steato-hepatitis) leads to scar tissue formation (fibrosis), the destruction of the normal liver structure (liver cirrhosis), which may or may not improve with abstinence and subsequently lead to liver cancer (hepatocellular carcinoma). In 2010, WHO suggests 10% of the adult population in the United States suffering from alcohol use disorders and liver cirrhosis is the 12^{th} leading cause of death in United States (Alcohol and Health, Focus on: Alcohol and the Liver, 2010, Vol. 33, No. 1 and 2, 87). It is known that 5% of the ethyl alcohol i.e. ethanol (hereinafter alcohol), ingested by a human being is excreted unchanged while the remaining 95% is degraded to acetaldehyde. Alcohol is rapidly absorbed from the GI tract. In fasting state the peak blood alcohol concentration reaches within 30 minutes. Distribution is rapid with tissue levels approximating blood concentrations. Liver accounts for nearly 90% of alcohol metabolism the remainder is excreted through the lungs & urine. The typical adult can metabolize 7-10 g of alcohol/hour (U.S. Pat. No. 7,666,909B2).

The primary pathway of alcohol metabolism, when consumed in low to moderate amount, is mainly catalyzed in the cytoplasm of hepatocytes by alcohol dehydrogenase (ADH) to form acetaldehyde. The accumulation of NADH (excess reducing equivalents) in the liver plays a role in liver damage seen more prominently with chronic alcohol use. Acetaldehyde produced through microsomal ethanol oxidation system (MEOS) initially represents a minor pathway of ethanol oxidation probably accounting for less than 10%, of the liver capacity to oxidize ethanol.

At higher alcohol level (>100 mg/dl), MEOS is dependent on CYP450 (2E1, 1A2 & 3A4) plays significant role in alcohol metabolism using NADPH as a cofactor & O_2. Catalase is especially capable of oxidizing ethanol in fasting state in the presence of hydrogen peroxide generating system. Acetaldehyde is oxidized in the liver via mitochondrial nicotinamide adenine dinucleotide (NAD^+) dependent aldehyde dehydrogenase (ALDH) to acetate. Activity of ALDH is nearly 3 times lower that ADH, hence accumulation of Acetaldehyde takes place. Acetate is further metabolized to acetyl CoA and can enter min TCA cycle or synthesis fatty acids. Each of these pathway results in the formation of free radicals (like reactive oxygen species {ROS}) with concomitant changes in the cells redox state (i.e. in the ratio of NADH to NAD^+ results in production of more NADH (Nicotinamide Adenine Dinucleotide (NAD^+) reduced by two electrons). The cell has a limited capacity to oxidize NADH back to NAD^+ in mitochondrial respiratory chain at the maximum capacity of this system, which determines the kinetics of the reaction. The redox state in relation to alcohol metabolism causes inhibition of NAD^+-mediated enzyme reactions typical to the normal metabolism of the hepatocyte. The citric acid cycle is affected the most as it gets inhibited. This leads to positive NADH/NAD ratio, which is considered the most important reason for the development of alcohol-induced fatty liver. The maximum capacity of the mitochondrial respiratory chain depends on the overall level of metabolism of the body. The consequence of altered redox state includes Hypoxia (oxygen deficit cell). The other plausible pathway of alcohol induced hepatotoxicity includes excess production of pro-inflammatory cytokines by gut-endotoxin stimulated Kupffer cells. ROS is mainly generated in association with the mitochondrial electron transport system; it is also produced by CYP2E1 and by activated Kupffer cells in the liver. Both acute and chronic alcohol consumption can increase ROS production, which leads to oxidative stress through a variety of pathways mentioned above [(Zakhari, S. Alcohol Research & Health, 2006, 29, 4, 245), (Wheeler M. D. et al, Free Radical Biology & Medicine, 2001, Vol. 31, No. 12, 1544), (Koop, D. R., Alcohol Research & Health, 2006, 29, 4, 274), (U.S. Pat. No. 7,666,909B2)].

The mechanisms involved by which alcohol causes cell injury are complex and combination of several inter-related pathways. ROS react primarily with the cell membrane (tight junction becomes more permeable) and in turn leaks lipopolysaccharides (LPS), as a consequence impaired gut structural integrity. The increases in transaminase enzymes [aspartate amino-transferase (AST) and alanine aminotransferase (ALT)] indicate cellular leakage and loss of functional integrity of cell membrane (Yue et. J, 2006). Loss of cellular integrity affects hepato-biliary function leading to elevated alkaline phosphatase (ALKP) activities with concurrent increase in serum bilirubin level and decrease in the total plasma protein content. Both increases and decreases in the levels of ROS can lead to apoptosis of hepatocytes (Wheeler M. D. Alcohol Res. Health, 2003; 27, 300). For the cell to function normally, GSH is critical to protect itself against ROS generated during activity of the mitochondrial respiratory chain. Alcohol consumption rapidly depletes GSH levels; alcohol interferes with Cytochrome c to leak from the mitochondria into the cytosol, which can activate enzymes known as caspases that can trigger apoptosis.

ROS induces LPO [ROS reacting with Malondialdehyde (MDA), 4-hydroxy nonenal (HNE)] and recognized as important starting place of hepatocytes damage. Endotoxin-activated Kupffer cells affects mitochondria leading to release of ROS (hydrogen peroxide radical, hydroxyl radical, particularly superoxide radical) and several cytokines (viz., Tumour necrotic factor {TNF-α}) leading to hepatocytes necrosis and apoptosis. It has been established by clinical studies that patients with alcoholic liver disease have increased levels of the inflammatory cytokines IL-1, IL-6, and TNF-α as well as the chemokine IL-8 and other cytokines.

Alcohol might enhance the sensitivity of hepatocytes, consequently which could lead to an increased production of ROS in the mitochondria. ROS could activate a regulatory protein called nuclear factor kappa B (NFκB), which plays critical role in regulation of immune response and controls the activities of numerous genes, including those that expresses TNF-α & its receptor as well as genes encoding proteins that promote apoptosis. Thus, a vicious cycle would be established in the hepatocytes: TNF-α promotes ROS production, which in turn activates NFκB, leading to enhanced production of additional TNF-α and its receptor as well as to production of factors that promote apoptosis. This cycle eventu-

ally alters the structure of the hepatocytes, impairs their function, and can lead to hepatocyte apoptosis. TNF-α also facilitates hepatocyte regeneration by promoting the proliferation [(Wheeler M. D. Alcohol Res Health, 2003; 27, 300), (Molina P., Happel, K. I., Zhang P., Kolls J. K., Nelson S., Focus on: alcohol and the immune system. Alcohol Res. Health, 2010, 33 (1 & 2), 97)1)].

TGF-β (transforming growth factor beta) might be involved in the development of alcohol-induced liver damage, which could cause the hepatocytes to produce molecules like trans-glutaminase, cytokeratins that are normally responsible for giving the cells their shapes. In excess, these molecules are cross-linked to form microscopic structures called Mallory bodies, which are markers of alcoholic hepatitis. TGF-β can also contribute to liver damage by activating stellate cells. In a normal state, these cells primarily serve to store fat and vitamin A in the liver. When activated, stellate cells produce collagen, the major component of scar tissue it leads to the development of liver fibrosis. Alcohol might trigger the activation of TGF-β and thereby contribute to the initiation of apoptosis if this molecule enters the blood in higher concentrations (Wheeler M. D., Alcohol Res. Health, 2003; 27, 300).

Acetaldehyde or ROS with DNA or protein or protein building blocks and ROS with MDA or MAA (mixed MDA-acetaldehyde-protein adduct) or HNE etc. in the cell could form stable or unstable adduct, which could be carcinogenic, immunogenic, induce inflammatory process, damage to the mitochondria etc. [(Zakhari, S. Alcohol Research & Health, 2006, 29 (4)245); (D. Wu, Alcohol Research & Health, 2106, 27, 4, 277); (Wheeler M. D., Alcohol Res. Health, 2003; 27, 300); (Molina P., Happel K. I., Zhang P., Kolls J. K., Nelson S., Focus on: alcohol and the immune system; (Alcohol Res. Health, 2010, 33, Vol. 1 & 2, 97); (Neuman M. G., Cytokine-central factor in alcoholic liver disease, Alcohol Res. Health, 2003, 27, 307)].

Varieties of endogenous enzymatic and non-enzymatic mechanisms have evolved to protect cells against ROS. This includes the superoxide dismutases (SOD), which remove O_2^-; Catalase (CAT) and the glutathione peroxidase (GP_X) system, which remove H_2O_2 and non-enzymatic low-molecular-weight antioxidants such as reduced glutathione (GSH), Vitamin E, Vitamin C, Vitamin A, Ubiquinone, Uric acid, and bilirubin. But these are capable to protect the cells to limited extent. Additional protection could be achieved by orally administrating the glutathione precursor like S-adenosyl-L-methionine (SAMe), N-acetyl cysteine (NAC) or anti-oxidant like Vitamin E. Vitamin C, plant bioactives (gallic acid, quercetinete) etc. (D. Wu, Alcohol Research & Health, 2006, 27, 4, 277).

PRIOR ART OF THE INVENTION

Literature discloses alcoholic beverages with various types of additives. The following literature exists in the field of this invention and has been considered in entirety.

US Patent Publication No. 20100086666 discloses alcoholic beverages in which a protein like casein hydrolysate to enhance smoother taste and gives some nutritional benefit to the consumer.

Das S. K. et. al. (Indian Journal of Biochemistry & Biophysics, 2010, vol 47, 32) describes concomitant treatment of resveratrol or vitamin E with alcohol in mice ameliorates; alcohol induced oxidative stress, angiogenesis process and aid in controlling immune-modulatory activity.

US Patent Publication No. 20100086666 discloses alcoholic beverages, which comprises phenol like epigallocatechingallate (EGCG), epigallocatechine (EGC), epicatechin (EC), epicatechingallate (ECG), proanthocyanin, tannin and quercetin etc. known to reduce oxidative stress by scavenging free radicals generated by alcohol.

U.S. Pat. No. 7,666,909B2 reveals alcoholic beverages comprising D-Glyceric acid and its salts enhancing the metabolism of alcohol reducing the adverse event caused due to alcohol consumption.

GA or Matrine (Mat) alkaloid isolated from *S. flavescens* alone, or GA+Mat, when administered to rat models of hepatic fibrosis induced by abdomen injection of dimethyl nitrosamine (DMN) in acetaminophen overdosed mice, reduces the mortality by attenuating acetaminophen-induced hepatotoxicity. This is probably due to reduced number and area of γ-GT positive foci. In addition, GA+Mat had a protective effect on immunosuppression, a strong non-specific anti-inflammatory effect, and an effect of reducing the incidence of sodium and water retention (W. Xu-yingae, Chemico-Biological Interactions, 181 (2009) 15-19).

WO No. 2008/055348A1 discloses that alcoholic beverages comprising turmeric reduces hangover.

Das S. K. et al. (Indian Journal of Experimental Biology, 2006, Vol 44, 791) reveals concomitant treatment of lecithin with Vitamin B complex or Vitamin E with alcohol in Wistar rats was performed. It was established that lecithin with Vitamin B complex with alcohol was promising therapeutic approach than Vitamin E with alcohol in allaying oxidative stress.

El-Fazaa S. et al. (Alcoholism & Alcoholism, 2006, Vol. 41, No 3, 236) exemplifies alcoholic beverages comprising resveratrol inhibits the alcohol induced lipid peroxidation and have protective effect against injury.

WO1989004165A1 or EP0336960A4 divulges alcoholic beverages with combination of any one or more sugars from the group consisting of D-Galactose, D-Lactose, D-Xylose. L-Fructose, D-Mannitol, D-Sorbitol, D-Glucose etc.

JP06014746 discloses alcoholic beverages comprising a glycoside of quercetin, divalent metallic ion and licorice extract (Glycyrrhizin). This beverage enhances alcohol metabolism and has hepatopathy-suppressive activity, due to ethanol and acetaldehyde. Thus, it reduces hangover.

CP Patent Publication No. 1736270 discloses liver-protecting drink constituting Chitosan oligosaccharide, glycyrrhizin, aqueous extract of kudzuvine flower and aqueous extract of hovenine.

US Patent Publication No. 20090196951 reveals alcoholic beverages comprising resveratrol a strong anti-oxidant, also activates the Sirtuin 1 (SIRT1) and Peroxisome proliferator-activated (PPAR)-gamma coactivator-1[PGC-1'] gene, which are key regulator of energy and metabolic homeostasis.

JP2008266203 and EP0502554 discloses an increase in amount of an enzyme activity of the Reactive oxygen species (ROS) scavenging enzyme group such as superoxide dismutase, catalase or peroxidase with one or more kinds of substances selected from the group consisting of Erythritol, Mannitol, Sorbitol and Xylitol.

CN1448497 discloses an alcoholic drink comprising of ethanol and Glycyrrhizin, but a synergistic mixture of alcohol with hepato-protectants that include certain sugar alcohols or sugars as integral part of the present composition, apart from Glycyrrhizin has not been described.

CN101744865 discloses a method of producing a liver protecting tablet comprising Xylitol and Glycyrrhizin. CN101744865 focuses on a method for preparing Xylitol liver tablets and nowhere demonstrates biological activity of such tablets. Moreover, the present patent is focused to an alcoholic beverage having reduced toxicity and a method of preparing the same. The present application demonstrates a

synergistic mixture of alcohol with hepato-protectants that include certain sugar alcohols or sugars as integral part of the composition and such synergistic mixture offers a good degree of hepato-protection.

Various other prior art documents are known (US 20080226787, U.S. Pat. No. 3,282,706, U.S. Pat. No. 1,720,329, U.S. Pat. No. 4,537,763, U.S. Pat. No. 8,524,785) where glycyrrhizin and sugar alcohols like Mannitol, Erythritol, Xylitol etc. have been used for imparting various functions in the beverages as non-nutritive sweetening agent having low calorific value or as flavoring agent, but the aspect of hepato-protection has not been disclosed.

Documents are available in prior art, which show that Glycyrrhizin, sugar alcohols and sugars are independently known to exhibit hepato-protective activity, but their combination to exhibit synergistic hepato-protection has not been reported so far. Applicant in this application reports for the first time synergistic activity imparted by a combination of 18β or α-Glycyrrhizin and sugar alcohols, more particularly 18β/α-Glycyrrhizin and D-Mannitol exhibiting exemplified synergistic hepato-protection to provide a beverage with reduced toxicity.

SUMMARY OF THE INVENTION

The present disclosure relates to an alcoholic beverage, particularly to alcoholic distilled spirits like vodka, flavored vodka, whisky, etc. having reduced hepato-toxicity comprising distilled alcohol, deionized water, glycyrrhizin and a sugar alcohol or sugar having a pH in the range of 4.0-9.0.

More particularly the invention provides an alcoholic beverage having reduced hepatotoxicity comprising distilled alcohol, deionized water, 18β-Glycyrrhizin or 18α-Glycyrrhizin and a sugar alcohol or sugar. The invention also relates to a process for the preparation of the said beverage. The exemplified reduced hepato-toxicity provided by the beverage has been achieved by synergistic hepato-protection exhibited by the combination of 18β or 18α-glycyrrhizin and a sugar alcohol/sugar present in the said alcoholic beverage.

OBJECTS OF THE INVENTION

An object of the present invention is to provide an alcoholic beverage having reduced toxicity.

Another object of the present invention is to provide an alcoholic beverage having synergistic activity and providing enhanced hepato-protection.

Yet another object of the present invention is to provide a beverage comprising hepato-protective agent(s) to achieve the reduced hepato-toxicity.

Yet another object of the present invention is to provide an alcoholic beverage comprising 18β-Glycyrrhizin or 18α-Glycyrrhizin to achieve the reduced hepato-toxicity.

Yet another object of the present invention is to provide an alcoholic beverage comprising hepato-protective agent(s) like sugar alcohols and sugar.

Yet another object of the present invention is to provide an alcoholic beverage comprising the sugar alcohols selected from D-Mannitol, D-Erythritol, D-Xylitol and like.

Yet another object of the present invention is to provide an alcoholic beverage comprising sugars selected from D-Xylose, D-Mannose, D-Sucrose and D-Lactose.

Still another object of the present invention is to provide an alcoholic beverage comprising pH adjusting agent(s), flavoring agent(s).

Further object of the present invention is provide an alcoholic beverage comprising optionally of the flavoring agents selected from vanilla, strawberry and like.

Still another object of the present invention is to provide an alcoholic beverage having acceptable taste, flavor, odor, clarity and buzz factor.

Another important object of the present invention is to provide a process for the preparation of alcoholic beverage composition comprising (a) alcohol or alcohol:water mixture (b) 18β-Glycyrrhizin/18α-Glycyrrhizin (c) sugar alcohol or sugar (d) pH adjusting agents and optionally a flavoring agent.

Still another object of the present invention provides an alcoholic beverage composition having enhanced hepato-protection.

The alcoholic beverage is for use in a method of amelioration of diseases involving acute and chronic alcoholic toxicity like alcoholic liver diseases (ALD) like steatosis.

DETAILED DESCRIPTION OF THE INVENTION

Accordingly, the present invention provides a beverage, more specifically an alcoholic beverage having reduced hepato-toxicity comprising distilled alcohol, deionized water, 18β or 18α-Glycyrrhizin and a sugar alcohol or sugar and having pH in the range of 4.0-9.0. More particularly the hepato-toxicity is caused by the intake of alcohol. The reduced hepatotoxicity of the beverage of the present invention is achieved by the enhanced hepato-protective activity provided by the synergistic combination of 18β or 18α-Glycyrrhizin and a sugar alcohol or Glycyrrhizin and a sugar incorporated in the said alcoholic beverage. The synergistic effect of the components has been established by dose dependent study for hepato-protection of 18β or 18α-Glycyrrhizin, sugar alcohol and a combination of Glycyrrhizin and sugar alcohol/sugar by performing experiment on animal models.

Ingredient Description:

Glycyrrhizin (or Glycyrrhizic acid or Glycyrrhizinic acid: abbreviated as GA) is the chief sweet-tasting constituent of *Glycyrrhiza glabra* (liquorice) root. It has also been given intravenously in Japan as a treatment for hepatitis C and as an emulsifier and gel-forming agent in foodstuff and cosmetics. Glycyrrhizin (GA) is a triterpenoid saponin glycoside. It is available as in racemic or pure form of 2 isomers: 18β-Glycyrrhizin and 18α-Glycyrrhizin. Hepato-protective mechanism of GA is due to its aglycone, glycyrrhetic acid, which inhibits both free radical generation as well as lipid peroxidation. 18α-GA has anti-hepato fibrosis effect—it is fre-

quently used as a hepato-protective agent. The sweetness of GA has a slower onset than sugar, and lingers in the mouth for some time. GA is partly absorbed as an intact drug. (W. Xuyinga et. al.) Chemico-Biological Interactions 181 (2009) 15-19), (T, Zing et. al. Chinese Journal of Modern Applied Pharmacy 2006, 02, 15-19). GA and its metabolites exhibit steroid-like anti-inflammatory activity, due, in part, to inhibition of Phospholipase A2 activity, an enzyme critical to numerous inflammatory processes. They inhibit hepatic metabolism of aldosterone and suppress hepatic 5-α-reductase. Because Cortisol and aldosterone bind with the same affinity to the mineralocorticoid receptor, an increase in renal Cortisol will result in a hyper-mineralocorticoid effect (Akamatsu, H. Planta Med., 1991, 57: 119-121), (Armanini, D., Clin. Endocrinol. 1983, 19: 609).

GA completely suppressed viral antigen expression possibly by causing a decrease in the negative charge on the cell surface and/or by decreasing the membrane fluidity thereby preventing Hepatitis A virus entry in cells by receptor mediated endocytosis (W. Xu-Yinga et. al., Chemico-Biological Interactions 181 (2009) 15-19).

GA induces phase II enzymes involved in the detoxification and excretion of carcinogenic or toxic substances and other antioxidant enzymes responsible for maintaining a balanced state between free radicals/oxidants and the antioxidants within the cellular environment. Oxidative injury in AR mice (Aldose reducrase deficient mice) is reduced by GA, by increasing GSH content and decreased MDA formation in a dose dependent manner. Concomitant decreases were observed in glutathione peroxidase (GPx), catalase (CAT), total antioxidant capacity (TAOC) and SOD activities in AR mice. IFN-α, or type II interferon, is a cytokine that is critical for innate and adaptive immunity against viral and intracellular bacterial infections and for tumour control. GA led to a significant, increase of IFN-α level in medicine treated mice. IL-4 is a cytokine that induces differentiation of naive helper T cells (Th0 cells) to Th2 cells. Upon activation by IL-4, Th2 cells subsequently produce additional IL-4 (Xiao-Lan Li *Int. J. Mol. Sci.* 2011, 12, 905). GA could increase infection resistance as [monocyte chemo-attractant (chemotactic) protein-1] is a CC chemokine MCP-1 inhibitor (United States Patent Application 20060116337).

The mice were treated intra-peritoneally with CCl_4 (0.5 ml/kg). They received GA (50, 300, 200, 400 mg/kg) 24 h and 0.5 h before and 4 h after administering CCl_4, This protection is likely due to the induction of heme oxygenase-1 and the down-regulation of pro-inflammatory mediators (Biol Pharm Bull. 2007, 30, 10, 11898). 18α-GA could dose-dependently inhibits CCl_4 induced liver fibrosis, by promoting the proliferation of hepatocytes, but inhibited that of Hepatic stellate cells (HSCs) GA blocks the translocation of NF-kB into the nucleus; this could suppress the activation and induce the apoptosis of HSCs (Q Ying, Med Sci. Monit., 2012, 18, 1: BR24).

GA was shown to attenuate histological hepatic changes and significantly reduced serum levels of AST, ALT, and lactic dehydrogenase (LDH), at all the indicated times. GA also significantly inhibited hepatocyte apoptosis by down-regulating the expression of caspase-3 and inhibiting the release of Cytochrome c from mitochondria into the cytoplasm. The anti-inflammatory activity of GA may rely on the inhibition of release of tumour necrosis factor-α, myeloperoxidase activity, and translocation of nuclear factor-kappa B into the nuclei. GA also up-regulated the expression of proliferating cell nuclear antigen, implying that it might be able to promote regeneration of livers harmed by LPS. In summary, GA may represent a potent drug protecting the liver against endotoxin-induced injury, especially after massive hepatectomy (Brazilian journal of Medical and Biological Research, 2007, 40, 1637). Pretreatment with GA (50 mg/kg) and the MMP inhibitor (5 mg/kg) suppressed increases in serum levels of ALT and AST in mice treated with LPS/Gal N due to a down-regulation of MMP-9 (J Pharm Pharmacol. 2008, 60, 1, 91).

The metabolic syndrome (MetS) is a cluster of metabolic abnormalities comprising visceral obesity, dyslipidaemia and insulin resistance (IR). Oral administration of 50 mg/kg of GA for one week could counteract the development of visceral obesity and improve dyslipidaemia via selective induction of tissue lipoprotein lipase (LPL), expression and a positive shift in serum lipid parameters respectively, and retard the development of IR associated with tissue steatosis (Lipids Health Dis. 2009, 29, 8, 31).

Diammoniumglycyrrhizinate (DG) protected mice against Concanavalin A (ConA)-induced elevation of serum ALT levels and apoptosis of hepatocytes; DG may possibly protect the liver from injury via two pathways: direct protection of hepatocytes from apoptosis through an IL-6 dependent way and indirect inhibition of T-cell-mediated inflammation through an IL-1 independent way (Int Immunopharmacol. 2007 October: 7(10): 1292).

Magnesium isoglycyrrhizinate 100 or 150 mg once daily, drugs are effective and safe treatment for chronic liver diseases (Zhoiighua Gan Zang Bing Za Zhi. 2009, 11, 847).

A sugar alcohol is a kind of alcohol prepared from sugars. These organic compounds are a class of polyols, also called polyhydric alcohol, polyalcohol, or glycitol. They are white, water-soluble solids that occur naturally and are used widely in the food industry as thickeners and sweeteners. Sugar alcohols such as Mannitol, Erythritol, Sorbitol, Xylitol etc., which are chemically stable can be used as a radical scavenger (hydroxyl radical). Similarly, it has been found that compounds like Erythritol, Mannitol, Sorbitol, Xylitol etc. up-regulated different types of superoxide dismutase (SOD) like Cu/Zn-, Mn- and EC-SOD isozymes. In particular, the SOD activity of the erythritol-added group increased by 2-5 times. Further it is reported that diabetics have a low SOD activity due to the Maillard reaction, because the Maillard reaction remarkably causes a decrease in the SOD activity (US Patent Application 20100037353 A1). Mannitol containing hyperosmolar solution has been shown to protect ethanol-induced gastric mucosal damage (Gharzouli K, Exp. Toxic. Pathol., 2001; 53: 175). Both rats and humans absorb and metabolize partially the Mannitol ingested in gastro intestinal tract (GIT). However, intestinal microflora convert Mannitol in to more absorbable form. In rat, absorbed mannitol is converted in to hepatic glycogen probably via fructose (J. Nutr. 1985, 115: 890). The mechanism of protecting living cells by Mannitol is not fully understood.

The beverage comprises of certain other ingredients like pH adjusting agent(s), and flavoring agent(s) etc.

Some important embodiments of the beverage of the present invention are as follows:

An important embodiment of the present invention relates to a beverage having reduced toxicity.

Yet another embodiment of the present invention relates to an alcoholic beverage having reduced hepato-toxicity.

Yet another embodiment of the present invention relates to an alcoholic beverage comprising hepato-protective agent(s) to achieve the reduced hepato-toxicity.

In an important embodiment of the present invention, the beverage comprises of 18β-Glycyrrhizin in combination with sugar alcohols selected from the group consisting D-Mannitol, D-Xylitol, D-Erythritol and mixtures thereof and reducing

or non-reducing sugars selected from D-Xylose, D-Mannose, D-Sucrose and D-Lactose and mixtures thereof.

In yet another important embodiment of the present invention, the beverage comprises of 18α-Glycyrrhizin in combination with sugar alcohols selected from the group consisting D-Mannitol, D-Xylitol, D-Erythritol and mixtures thereof.

In an important embodiment, the beverage composition comprises 18β-Glycyrrhizin in the range of 0.05 to 0.4%, preferably 0.1 to 0.3% and D-Mannitol, D-Xylitol, D-Erythritol, D-Xylose, D-Mannose, D-Sucrose, D-Lactose and mixture thereof is in the range of 0.5 to 3.0%, preferably 1.0 to 2.5%.

In an important embodiment, the beverage composition comprises 18β-Glycyrrhizin in range of 0.05 to 0.3%, preferably 0.1 to 0.3% and D-Mannitol, D-Xylitol, D-Erythitol and mixtures thereof is in the range of 0.5 to 3.0%, preferably 1.0 to 2.5%.

In an important embodiment, the most preferable combination of hepato-protective agents is a combination of 18β-Glycyrrhizin or 18α-Glycyrrhizin and D-Mannitol.

In an important embodiment, the beverage composition comprises 18β-Glycyrrhizin in the range of 0.05 to 0.3% and the D-Mannitol is in the range of 0.5 to 3.0% and preferably 18β-Glycyrrhizin in the range of 0.1 to 0.3% and the D-Mannitol is in the range of 1.0 to 2.5%.

In an important embodiment, the beverage composition comprises 18α-Glycyrrhizin in the range of 0.1 to 0.3% and the D-Mannitol in the range of 1.0 to 2.5%.

In yet another embodiment, the process for the preparation of alcoholic beverage composition comprising steps of (a) obtaining alcohol or water or a mixture thereof, (b) mixing 18β-Glycyrrhizin or 18α-Glycyrrhizin with the alcohol or water or a mixture of alcohol and water of step (a), (c) adding sugar alcohol or sugar to the mixture of step (b), (d) adjusting the pH of the resulting solution of step (c) between 4.0-9.0, (e) optionally adding the flavoring agent and (t) obtaining the required alcoholic beverage composition.

Still another embodiment of the present invention is to provide an alcoholic beverage composition comprising the pH adjusting agent(s).

In yet another embodiment, the pH adjusting agent is an organic or inorganic base/buffer, preferably selected from potassium sorbate or sodium phosphate (monobasic or dibasic or tribasic).

Further embodiment of the present invention provides a beverage optionally comprising of flavoring agents selected from, vanilla and strawberry.

Still another embodiment of the present invention is to provide a beverage having acceptable taste, flavor, odor, clarity and buzz factor.

In a further embodiment of the present invention variation in dosages of sugar alcohols, glycyrrhizin and a combination of sugar alcohols and 18β or 18α-Glycyrrhizin has also been evaluated for its hepato-protective activity.

The scope of the present invention also includes the study in respect of acute and chronic hepatotoxicity caused by the variation in the alcohol dosage and its time of duration in administration.

Still another embodiment of the beverage composition relates to providing reduced hepato-toxicity.

Yet another embodiment of the beverage composition is the use in a method of amelioration of diseases involving acute and chronic toxicity such as alcoholic liver diseases (ALD) like steatosis, steatohepatitis, fibrosis, liver cirrhosis and hepatocellular carcinoma etc. which are caused by alcohol induced toxicity.

Another important embodiment of the present invention is that the beverage composition can be packed as ready-to-drink produce in food grade bottles, cans, tetra packs, pouches, etc. The packaging can be done by conventional methods.

For the establishment of synergism existing in the formulation of the present invention, markers/marker enzymes viz. SOD, Catalase, GPx, TNF-α were primarily taken into consideration for evaluating the % synergism. However, enzymes ALT, AST, ALKP and MDA were also analyzed to support the same.

Reasons for Estimating ALT, AST, ALKP:

Chronic misuse of alcohol changes marker enzymes of liver functions such as serum aspartate aminotransferase and alanine aminotransferase (AST, ALT), alkaline phosphatase (ALKP) and so these enzymes were studied.

ALT and AST are found in hepatocytes but AST is also found in skeletal and myocardial cells. In alcohol related liver damage, the AST is elevated more than the ALT, at least in part as a reflection of alcohol related skeletal damage. This is the reverse of the normal pattern in acute hepatocellular disease (for example acute viral hepatitis) where the ALT exceeds the AST.

ALKP is an enzyme in the cells lining the biliary ducts of the liver. ALKP levels in plasma will rise almost concomitantly with liver disease related with altered bile production and/or secretion and chronic liver diseases.

Reasons for Estimating Oxidative Stress Markers (MDA, Antioxidant Enzymes [SOD, CAT, Glutathione Peroxidase Etc.] Reduced Glutathione [GSH]):

Alcohol metabolism in the liver results in the formation reactive oxygen species (ROS). Alcohol also stimulates the activity of cytochrome P450, which contribute to ROS production. Further, alcohol can alter the levels of certain metals in the body, thereby facilitating ROS production. Finally, alcohol reduces the levels of agents that can eliminate ROS (i.e., endogenous antioxidants). The resulting state of the cell, known as oxidative stress, can lead to cell injury. ROS production and oxidative stress in liver cells play a central role in the development of alcoholic liver disease.

MDA (Malondialdehyde) is the end product of cell membrane lipid peroxidation. ROS degrade (oxidative degradation) polyunsaturated fatty acids of cell membrane resulting cell damage. The extent of lipid peroxidation can be well correlated with tissue MDA content.

SOD (Superoxide dismutase) catalyzes the breakdown of the superoxide radical into oxygen and hydrogen peroxide. Liver cells are enriched with SOD as it is the major organ related with metabolism numerous substances.

CAT (Catalase) catalyzes the conversion of hydrogen peroxide (H_2O_2) to water and oxygen. This enzyme is localized to peroxisomes in most eukaryotic cells.

GPx (Glutathione peroxidase) is the most abundantly available in the cytoplasm of most of the cells. It neutralizes hydrogen peroxide (H_2O_2) in presence of GSH.

$$2GSH + H_2O_2 \xrightarrow{GPx} GS\text{-}SG + 2H_2O_2$$

(GSH-reduced glutathione, GSSG-oxidized glutathione)

GSH is the most abundant antioxidant in aerobic cells. GSH is critical for protecting the cells from oxidative stress, acting as a free radical scavenger and inhibitor of lipid peroxidation. (GSH also participates in the degradation of H_2O_2 by glutathione peroxidases (GPx). The ratio of reduced glutathione (GSH) to oxidized glutathione (GSSG) is an indicator of cellular health (status of cellular redox potential). In normal

healthy conditions GSH constituting nearly 90% of cellular glutathione (i.e., GSH/GSSG is around 9). However, the GSH/GSSG ratio is reduced in ROS related disorders.

Reasons for Estimating Tumor Necrotic Factor Alpha (TNF-α):

Alcohol consumption increases the translocation of endotoxins from intestine to portal circulation and interacts with Kuppfer cells (immunocytes) leading to secretion of several pro-inflammatory cytokines including tumor necrotic factor alpha (TNF-α).

Based on the Above Description, we Identified Some Key Marker and Justify the Importance of the Parameter Chosen: SOD, Catalase & GPx: In system SOD catalyzes the dismutation of superoxide to H_2O_2. GPx and Catalase then independently convert this H_2O_2 to water. SOD together with GPx and catalase form the main enzyme defense against harmful effect of ROS.

GSH is the main endogenous antioxidant that protects cells from xenobiotics including alcohol. Alcohol is known to deplete GSH levels on the process to neutralize oxidants. Apart from this, endogenous glutathione-glutathione peroxidase system acts as an important antioxidants and cyto-protective machinery in the hepatocytes exposed to ethanol. Thus, depletion of cellular GSH level plays an important role in ethanol-mediated hepato-cellular dysfunction.

The following tables (1 to 9) illustrate the % of hepatoprotection of individual ingredients, combination of ingredients and the % synergism exhibited using respective combinations. All animal experiments were conducted for a period of one month by per oral administration of 2.5 g/kg dose of alcohol.

The data provided in the above tables clearly indicates that the 18β-GA/D-Mannitol combination exhibits superior order of synergism over the combination of 18β-GA/D-Erythritol and 18β-GA/Xylitol combinations.

The data provided in the above tables also indicates that overall the 18β-GA/D-Mannitol combinations exhibit almost similar order of synergism as that of 18α-GA/D-Mannitol combinations.

Also it can be concluded that the combination of 18β-GA/reducing or non-reducing mono or disaccharide has exhibited lesser degree of synergistic effect.

The present invention is illustrated with the following examples. However, it should be understood that the scope of the present invention is not limited by the examples in any manner. It will be appreciated by any person skilled in this art that the present investigation includes following examples and further can be modified and altered within the scope of the present invention.

Materials and Methods

Reagents

Distilled ethanol was obtained from Bengal Chemicals, West Bengal, India. Biochemical kits like AST, ALT, ALKP and total protein were obtained from Span Diagnostics Ltd. Surat, India. Time course study of oxidative and nitrosative stress and antioxidant enzymes in $K_2Cr_2O_7$-induced nephrotoxicity. BMC Nephrol., 6: 4). TNF-α was estimated by standard procedures as mentioned in Rat TNF-α ELISA kit (Bio Legend, Inc. San Diego, Calif., USA).

All the chemicals used in the present study were of analytical grade and obtained from the following companies: Sigma (St. Louis, Mo. USA), Merck (Mumbai, India), S. D. Fine Chemicals (Mumbai, India) and Qualign (Mumbai, India).

Alcohol Induced Sub-Acute Hepatotoxicity in Rats

Male Wistar albino rats weighing 150-200 g are procured from local registered traders (CPCSEA Regd No. 1443/po/6/4/CPCSEA), Kolkata. India and were acclimatized for 7 days at standard housing condition (26° C.±2° C., 60-70% RH with 12±1 hours light and dark cycle). Animals were fed with commercially available diet (Upton India Pvt. Ltd, India) and water ad-libitum during the experiment period.

EXAMPLES

Example 1

a) Model for Biological Testing

Male Wistar albino rats weighing 150-200 g are procured and randomly divided into groups consisting of six animals in each group. Sub-acute toxicity is induced by alcohol in rats by oral administration of 25% alcohol (2.5 gm/kg/day, p.o.) for 28 days and this group served as the negative control and the positive control group received distilled water only.

b) Preparation of Drug Solution

All drug solutions were prepared in 15-40% aqueous alcohol, adjusting the pH in the range of 4.0-9.0 for evaluation of hepato-protective activity. This solution is further diluted with distilled water to obtain 25%, aqueous alcoholic solution and administered orally by gavage to different rats group of step (a).

c) Evaluation of Hepato-Protective Activity

On day 28th day the animals are anaesthetized with ether and blood samples are collected by cardiac puncture and the serum is used for the assay of marker enzymes viz. serum alanine aminotransferase (ALT), aspartate aminotransferase (AST), alkaline phosphatase (ALP). The rats are sacrificed by exposure to an overdose of ether, immediately after the collection of blood; their livers are removed, washed in cold saline. Part of the liver is used for preparation of liver homogenate in phosphate buffer (pH 7.4). The supernatant is used for the estimation of malondialdehyde (MDA), super oxide dismutase (SOD), catalase (CAT), reduced glutathione (GSH), and Glutathione peroxidase (GPx).

Example 2

D-Mannitol (0.5 g) is dissolved in aqueous alcohol (100 ml) to provide 0.5% solution. This solution is administered in several portions to one of the rats group of Example (1a). The administration is carried out over a period of 28 days; each day 10 ml sample is diluted with 6 nil distilled water to make 25% aqueous alcoholic solution (16 ml) and fed orally (10 ml/kg/day). Evaluation of hepato-protective activity is carried out as per Example (1c).

Mean % hepato-protection:	
ALT, AST and ALKP	12.26%
SOD, CAT and GPx	12.71%
GSH	10.35%
Hepatic MDA	19.17%
TNF-α	7.19%

Example 3

D-Mannitol (2.5 g) is dissolved in aqueous alcohol (100 ml) to provide 2.5% solution. This solution is administered in several portions to one of the rats group of Example (1a). The administration, sample dilution, oral feeding and evaluation of hepato-protective activity is carried out as mentioned in Example 2 and as per Example (1c).

Mean % hepato-protection:	
ALT, AST and ALKP	29.71%
SOD, CAT and GPx	35.83%
GSH	31.53%
Hepatic MDA	50.80%
TNF-α	31.46%

Example 4

18β-Glycyrrhizin (0.1 g) is dissolved in aqueous alcohol (100 ml) to provide 0.1% solution. This solution is administered in several portions to one of the of rats group of Example (1a). The administration, sample dilution, oral feeding and evaluation of hepato-protective activity is carried out as mentioned in Example 2 and as per Example (1c).

Mean % hepato-protection	
ALT, AST and ALKP	8.38%
SOD, CAT and GPx	11.45%
GSH	3.29%
Hepatic MDA	15.97%
TNF-α	7.64%

Example 5

D-Mannitol (2.5 g) and 18β-Glycyrrhizin (0.1 g) are dissolved in aqueous alcohol (100 ml) to provide 2.6% solution. This solution is administered in several portions to one of the rats group of Example (1a). The administration, sample dilution, oral feeding and evaluation of hepato-protective activity is carried out as mentioned in Example 2 and as per Example (1c).

Mean % hepato-protection:	
ALT, AST and ALKP	40.35%
SOD, CAT and GPx	60.15%
GSH	48.24%
Hepatic MDA	85.62%
TNF-α	50.56%

Example 6

D-Mannitol (2.5 g) and 18β-Glycyrrhizin (1.0 g) are dissolved in aqueous alcohol (100 ml) to provide 3.5% solution. This solution is administered in several portions to one of the rats groups of Example 1(a). The administration, sample dilution, oral feeding and evaluation of hepato-protective activity is carried out as mentioned in Example 2 and as per Example (1c).

Mean % hepato-protection:	
ALT, AST and ALKP	52.35%
SOD, CAT and GPx	78.75%
GSH	83.29%
Hepatic MDA	93.29%
TNF-α	87.64%

Example 7

D-Mannitol (0.5 g) and 18β-Glycyrrhizin (0.1 g) are dissolved in aqueous alcohol (100 ml) to provide 0.6% solution. This solution is administered in several portions to one of the rats group of Example (1a). The administration, sample dilution, oral feeding and evaluation of hepato-protective activity is carried out as mentioned in Example 2 and as per Example (1c).

Mean % hepato-protection:	
ALT, AST and ALKP	21.0%
SOD, CAT and GPx	25.34%
GSH	17.64%
Hepatic MDA	39.63%
TNF-α	19.16%

Example 8

D-Mannitol (3.0 g) and 18β-Glycyrrhizin (0.1 g) are dissolved in aqueous alcohol (100 ml) to provide 3.1% solution. This solution is administered in several portions to one of the rats group of Example (1a). The administration, sample dilution, oral feeding and evaluation of hepato-protective activity is carried out as mentioned in Example 2 and as per Example (1c).

Mean % hepato-protection:	
ALT, AST and ALKP	37.23%
SOD, CAT and GPx	58.15%
GSH	45.53%
Hepatic MDA	70.87%
TNF-α	47.20%

Example 9

D-Mannitol (2.5 g) and 18β-Glycyrrhizin (0.4 g are dissolved in aqueous alcohol (100 ml) to provide 2.9% solution. This solution is administered in several portions to one of the rats group of Example (1a). The administration, sample dilution, oral feeding and evaluation of hepato-protective activity is carried out as mentioned in Example 2 and as per Example (1c).

Mean % hepato-protection:	
ALT, AST and ALKP	53.15%
SOD, CAT and GPx	79.83%
GSH	76.38%
Hepatic MDA	80.41%
TNF-α	81.62%

Example 10

D-Mannitol/D-Xylitol/D-Erythritol (1.0 g) and 18β-Glycyrrhizin (0.1 g) are dissolved in aqueous alcohol (100 ml) to provide 1.1% solution. This solution is administered in several portions to one of the rats group of Example (1a). The administration, sample dilution, oral feeding and evaluation of hepato-protective activity is carried out as mentioned in Example 2 and as per Example (1c).

Mean % hepato-protection:			
	Sugar alcohols		
Enzymes/Markers	D-Mannitol	D-Xylitol	D-Erythritol
ALT, AST and ALKP	29.13%	27.19%	24.48%
SOD, CAT and GPx	39.33%	38.26%	35.64%
GSH	29.58%	28.19%	28.25%
Hepatic MDA	55.41%	50.02%	46.38%
TNF-α	32.68%	29.72%	30.37%

Example 11

D-Mannitol/D-Xylitol/D-Erythritol (2.5 g) and 18β-Glycyrrhizin (0.3 g) are dissolved in aqueous alcohol (100 ml) to provide 2.8% solution. This solution is administered in several portions to one of the rats group of Example (1a). The administration, sample dilution, oral feeding and evaluation of hepato protective activity is carried out as mentioned in Example 2 and as per Example (1c).

Mean % hepato-protection:			
	Sugar alcohols		
Enzymes/Markers	D-Mannitol	D-Xylitol	D-Erythritol
ALT, AST and ALKP	49.40%	46.90%	52.68%
SOD, CAT and GPx	71.57%	71.18%	71.86%
GSH	61.95%	60.61%	66.14%
Hepatic MDA	76.54%	80.52%	80.30%
TNF-α	69.63%	55.65%	64.36%

Example 12

DI-Mannose/D-Xylose/D-Lactose/D-Sucrose (2.5 g) and 18β-Glycyrrhizin (0.3 g) are dissolved in aqueous alcohol (100 ml) to provide 2.8% solution. This solution is administered in several portions to one of the rats group of Example (1a). The administration, sample dilution, oral feeding and evaluation of hepato-protective activity is carried out as mentioned in Example 2 and as per Example (1c).

Mean % hepato-protection:				
	Sugars			
Enzymes/Markers	D-Mannose	D-Xylose	D-Lactose	D-Sucrose
ALT, AST and ALKP	33.88%	32.28%	34.60%	31.40%
SOD, CAT and GPx	42.02%	53.23%	47.19%	41.30%
GSH	37.58%	34.27%	38.16%	33.41%
Hepatic MDA	59.27%	52.64%	57.88%	56.53%
TNF-α	43.19%	38.10%	39.55%	40.12%

Example 13

D-Mannose/D-Xylose/D-lactose/D-Sucrose (1.0 g) and 18β-Glycyrrhizin (0.1 g) are dissolved in aqueous alcohol (100 ml) to provide 1.1% solution. This solution is administered in several portions to one of the rats group of Example (1a). The administration, sample dilution, oral feeding and evaluation of hepato-protective activity is carried out as mentioned in Example 2 and as per Example (1c).

Mean % hepato-protection:				
	Sugars			
Enzymes/Markers	D-Mannose	D-Xylose	D-Lactose	D-Sucrose
ALT, AST and ALKP	15.71	16.84%	16.75%	14.63%
SOD, CAT and GPx	18.05	20.97%	19.47%	18.32%
GSH	11.02	10.90%	8.57%	10.65%
Hepatic MDA	28.82	22.23%	25.10%	25.87%
TNF-α	17.07	15.60%	17.20%	15.14%

Example 14

D-Mannitol (1.0 g) and 18α-Glycyrrhizin (0.1 g) are dissolved in aqueous alcohol (I 00 ml) to provide 1.1% solution. This solution is administered in several portions to one of the rats group of Example (1a). The administration, sample dilution, oral feeding and evaluation of hepato-protective activity is carried out as mentioned in Example 2 and as per Example (1c).

Mean % hepato-protection:	
ALT, AST and ALKP	30.97%
SOD, CAT and GPx	42.42%
GSH	32.74%
Hepatic MDA	54.16%
TNF-α	34.05%

Example 15

D-Mannitol (2.5 g) and 18α-Glycyrrhizin (0.3 g) are dissolved in aqueous alcohol (100 ml) to provide 2.8% solution. This solution is administered in several portions to one of the rats group of Example (1a). The administration, sample dilution, oral feeding and evaluation of hepato-protective activity is carried out as mentioned in Example 2 and as per Example (1c).

Mean % hepato-protection:	
ALT, AST and ALKP	46.49%
SOD, CAT and GPx	69.06%
GSH	57.44%
Hepatic MDA	78.80%
TNF-α	68.1%

Example 16

Method of Preparation:

0.1 to 0.4 grams of 18β/α-Glycyrrhizin is dissolved in 15-40% alcohol or alcohol:water mixture (in 100 ml). To this solution (0.5 to 3.0 grams) of sugar alcohol or sugar is added. The resulting solution is mixed thoroughly to obtain a clear solution. Thereafter the pH of the resulting solution is adjusted to between 4.0-9.0 and optionally desired flavoring agent (vanilla) is added to obtain the final alcoholic beverage composition.

The expansion for the abbreviations used in this application is enumerated as below:

GA: Glycyrrhizin (Glycyrrhizic acid or Glycyrrhizinic acid or 18β-Glycyrrhizin)

Man: Mannitol

Xyl: Xylitol

Ery: Erythitol
Mans: Mannose
Suc: Sucrose
Xyls: Xylose
Lac: Lactose
SOD etc: SOD, CAT & GPx
ALT etc: ALT, AST and ALKP
Mat: Matrine

ADVANTAGES OF THE PRESENT INVENTION

1. The alcoholic beverage of the present invention has better hepato-protection.
2. The alcoholic beverage of the present invention has an acceptable odor, taste, clarity and acceptable buzz factor.

What is claimed is:

1. An alcoholic beverage composition providing synergistic hepato-protection, the alcoholic beverage comprising:

a) a first hepato-protective agent;

b) alcohol or an alcohol-water combination; and

c) a second hepato-protective agent;

d) wherein said first hepato-protective agent comprises 18α-Glycyrrhizin in a mass concentration range of 0.05% to 0.3% or 18β-Glycyrrhizin in a mass concentration range of 0.05% to 0.4% or a combination thereof;

e) wherein said second hepato-protective agent comprises at least one sugar or at least one sugar alcohol in a mass concentration range of 0.5% to 3.0%.

2. The alcoholic beverage composition as claimed in claim **1**, wherein said second hepato-protective agent comprises at least one sugar alcohol selected from the group consisting of D-Mannitol, D-Xylitol, and D-Erythritol, or a combination thereof.

3. The alcoholic beverage composition as claimed in claim **1**, wherein said second hepato-protective agent comprises at least one sugar selected from the group consisting of D-Sucrose, D-Mannose, D-Xylose and D-Lactose, or a combination thereof.

4. The alcoholic beverage composition as claimed in claim **2**, wherein: said first hepato-protective agent comprises 18α-Glycyrrhizin in a mass concentration range of 0.05% to 0.3%; and said sugar alcohol is in a mass concentration range of 0.5% to 3.0%.

5. The alcoholic beverage composition as claimed in claim **2**, wherein: said first hepato-protective agent comprises 18α-Glycyrrhizin in a mass concentration range of 0.1% to 0.3%; and said sugar alcohol is in a mass concentration range of 1.0% to 2.5%.

6. The alcoholic beverage composition as claimed in claim **3** wherein: said first hepato-protective agent comprises 18α-Glycyrrhizin in a mass concentration range of 0.05 to 0.3%; and said sugar is in a mass concentration range of 0.5% to 3.0%.

7. The alcoholic beverage composition as claimed in claim **3**, wherein: said first hepato-protective agent comprises 18α-Glycyrrhizin in a mass concentration range of 0.1% to 0.3%; and said sugar is in a mass concentration range of 1.0% to 2.5%.

8. The alcoholic beverage composition as claimed in claim **1**, further comprising at least one pH adjusting agent.

9. The alcoholic beverage composition as claimed in claim **1**, herein said alcoholic beverage composition further comprises at least one flavoring agent.

10. A process for the preparation of alcoholic beverage composition of claim **1**, comprising steps of (a) obtaining alcohol or alcohol-water combination, (b) mixing 18β-Glycyrrhizin or 18α-Glycyrrhizin with the alcohol or alcohol-water combination of step (a), (c) adding sugar alcohol or sugar to the mixture of step (b), (d) adjusting pH of resulting solution of step (c) between 4.0-9.0, (e) optionally adding flavoring agent and (f) obtaining the alcoholic beverage composition.

11. A method of using the alcoholic beverage composition as claimed in claim **1**, comprising the step of consuming the alcoholic beverage composition by a human, for providing reduced hepato-toxicity in said human.

12. The alcoholic beverage composition as claimed in claim **1** for use in a method of amelioration of diseases involving acute and chronic toxicity caused by alcohol consumption.

13. The alcoholic beverage composition claimed in claim **9**, wherein said flavoring agent comprises vanilla flavor or strawberry flavor.

14. The alcoholic beverage composition as claimed in claim **2**, wherein: said first hepato-protective agent comprises 18β-Glycyrrhizin in a mass concentration range of 0.05% to 0.4%; and said sugar alcohol is in a mass concentration range of 0.5% to 3.0%.

15. The alcoholic beverage composition as claimed in claim **2**, wherein: said first hepato-protective agent comprises 18β-Glycyrrhizin in a mass concentration range of 0.1% to 0.3%; and said sugar alcohol is in a mass concentration range of 1.0% to 2.5%.

16. The alcoholic beverage composition as claimed in claim **3**, wherein: said first hepato-protective agent comprises 18β-Glycyrrhizin in a mass concentration range of 0.05 to 0.4%; and said sugar is in a mass concentration range of 0.5% to 3.0%.

17. The alcoholic beverage composition as claimed in claim **3**, wherein: said first hepato-protective agent comprises 18β-Glycyrrhizin in a mass concentration range of 0.1% to 0.3%; and said sugar is in a mass concentration range of 1.0% to 2.5%.

18. The alcoholic beverage composition as claimed in claim **1**, wherein said first hepato-protective agent comprises 18β-Glycyrrhizin or 18α-Glycyrrhizin and said second hepato-protective agent comprises D-Mannitol.

19. The alcoholic beverage composition as claimed in claim **18**, wherein: said first hepato-protective agent comprises 18β-Glycyrrhizin in a mass concentration range of 0.05% to 0.4%; and said D-Mannitol is in a mass concentration range of 0.5% to 3.0%.

20. The alcoholic beverage composition as claimed in claim **18**, wherein: said first hepato-protective agent comprises 18β-Glycyrrhizin in a mass concentration range of 0.1% to 0.3%; and said D-Mannitol is in a mass concentration range of 1.0% to 2.5%.

21. The alcoholic beverage composition as claimed in claim **18**, wherein: said first hepato-protective agent comprises 18α-Glycyrrhizin in a mass concentration range of 0.05% to 0.3%; and said D-Mannitol is in a mass concentration range of 0.5% to 3.0%.

22. The alcoholic beverage composition as claimed in claim **18**, wherein: said first hepato-protective agent comprises 18α-Glycyrrhizin in a mass concentration range of 0.1% to 0.3%; and said D-Mannitol is in a mass concentration range of 1.0% to 2.5%.

23. The alcoholic beverage composition as claimed in claim **8**, wherein said pH adjusting agent comprises an organic or inorganic base/buffer selected from the group consisting of potassium sorbate, sodium dihydrogen phosphate, sodium hydrogen phosphate, and trisodium phosphate.

Abstract
Purpose Animal studies have shown the potential benefits of mannitol as renoprotective during warm ischemia; it may have antioxidant and anti-inflammatory properties and is sometimes used during partial nephrectomy (PN) and live donor nephrectomy (LDN). Despite this, a prospective study on mannitol has never been performed. The aim of this study is to document patterns of mannitol use during PN and LDN.

Materials and methods A survey on the use of mannitol during PN and LDN was sent to 92 high surgical volume urological centers. Questions included use of mannitol, indications for use, physician responsible for administration, dosage, timing and other renoprotective measures.

Results Mannitol was used in 78 and 64 % of centers performing PN and LDN, respectively. The indication for use was as antioxidant (21 %), as diuretic (5 %) and as a combination of the two (74 %). For PN, the most common

dosages were 12.5 g (30 %) and 25 g (49 %). For LDN, the most common doses were 12.5 g (36.3 %) and 25 g (63.7 %). Overall, 83 % of centers utilized mannitol, and two (percent or centers??) utilized furosemide for renoprotection.

Conclusions A large majority of high-volume centers performing PN and LDN use mannitol for renoprotection. Since there are no data proving its value nor standardized indication and usage, this survey may provide information for a randomized prospective study.

Keywords Mannitol · Live donor nephrectomy · Partial nephrectomy · Renoprotective agent · Diuretics

Introduction

Both in living donor (LDN) and partial nephrectomy (PN), preserving renal function is crucial. It is well known that warm ischemia-time affects renal function by organ-induced ischemia and subsequent Ischemia–Reperfusion Injury (IRI). IRI is known to affect renal function which may lead to organ failure. Its biological effect lays on sub-cellular injuries with generation of free radicals leading to acute tubular necrosis, reduced glomerular filtration rate (GFR) and, eventually, renal failure [1–4]. There has been evidence that implementation of diuresis may in fact reduce the warm ischemia-related renal damage [1, 3, 5–8]. Therefore, diuretics are commonly used in partial and live donor nephrectomy. It has been speculated that mannitol may have some advantages over other diuretics due to a possible antioxidant activity [9, 10]. Despite this, there is insufficient evidence to recommend and standardize the use of mannitol.

The aim of this study is to document the trend in mannitol use during partial and live donor nephrectomy, through an international survey sent to high-volume tertiary centers.

Materials and methods

A survey on the use of mannitol during partial and live donor nephrectomy was sent by e-mail to 92 high surgical volume urological centers around the world. Survey was performed considering indications, doses and modalities of infusion and use of mannitol reported in literature. The survey was distributed and returned via e-mail in February 2011. We initially queried about the type of Institution and related surgical activities. Questions specifically related to the use of mannitol included the following: if mannitol was utilized in surgical practice, indications (partial and or donor nephrectomy), rationale of using mannitol, physician in charge for mannitol administration (urologist, nephrologist or anesthetist), dose administered in case of partial or donor nephrectomy, timing of administration (before or after clamping), usage of other type of kidney protectors and number of partial of donor nephrectomies performed per year at the corresponding Institution.

Results

We obtained surveys from 47 centers (51 %). Forty-seven of 47 (100 %) and 17 of 47 (36 %) performed partial and live donor nephrectomy, respectively. Mannitol was used in 78.7 and 64.7 % of centers performing partial and live donor nephrectomy, respectively. The indication for mannitol use was as an antioxidant (20.5 %), as a diuretic (5.2 %) and as a combination of the two (74.3 %). The physician in charge of mannitol administration was the urologist in 53.8 % of the cases, the anesthesiologist in 30.7 % of the cases and both in 12.8 %. In case of partial nephrectomy, dosages administered were 12.5 g in 29.7 % of the cases, 25 g in 48.6 % and different dosages in 21.7 % of the cases. The timing of mannitol administration was before clamping in 75.6 % of the cases, after clamping in 5.4 % and both before clamping and at reperfusion in 19 % of the cases.

In case of live donor nephrectomy, it was administered at dosages of 12.5 g in 36.3 % of the cases and at 25 g in 63.7 %. The timing for administration was before clamping in all cases.

Overall, 83 % ($N = 39$) of the centers utilized mannitol. Of the centers not using mannitol, two utilized Furosemide as kidney protector instead of mannitol.

Discussion

Ischemia, and subsequent reperfusion injury, is a consequence of LDN and PN with arterial clamping. In both circumstances, the induced injury in the renal parenchyma is caused by the alteration of the microcirculatory compliance and by the increase in the perfusion pressure. This effect is magnified in cases of prolonged ischemia-time. Therefore, it is widely accepted that the duration of the ischemia-time is proportionally correlated with the magnitude of ischemia/reperfusion injury [2]. Although the understanding of the cell-death mechanism subsequent to ischemia/reperfusion injury has been deeply investigated during the last few years [1–3, 11], little is known about the efficacy of strategies to reduce this event during LDN and PN. Hypothermic kidney storage (ice) is the principal secure method for kidney preservation. It has been shown that hypothermia reduces cellular metabolism and slows the process that impair cell viability [1].

Diuretics have been also evaluated for kidney protection during LDN and PN. Some authors have evaluated the role of mannitol and other diuretics as kidney protector agents, and there is still a controversial opinion on its real efficacy as kidney protector agent [4, 8, 12–15]. The rationale of giving diuretics during PN or LDN is that a non-oliguric state may be maintained by promoting diuresis and protect the kidney from ischemic/reperfusion injury; furthermore, diuretics have been shown to prevent tubular obstruction, to reduce medullary oxygen consumption and to increase renal blood flow [16]. A multinational survey [14] has recently confirmed that 70 % of intensivists use loop diuretics in a large spectrum of acute renal injury conditions like major surgery, sepsis, shock, contrast or drug-induced nephrotoxicity.

Few prospective randomized trials have addressed the role of diuretics in prevention of acute renal injury, and most of them have been conducted to study the effect of contrast administration [17] and cardiac surgery [18]. Unfortunately, the results have shown that diuretics offer no protection against contrast-induced nephropathy, and in cardiac surgery, higher postoperative creatinine levels were seen in patients treated with furosemide [18]. Similar results were published in four different randomized controlled trials examining the role of diuretics in patients with established renal failure treated in intensive care unit, with no improvements reported in recovering renal function or in decreasing mortality [19–21].

Moreover, three meta-analyses published similar results and noted a significant higher risk of side effects (like hearing-loss) [13, 15, 22] for patients receiving diuretics treatment in cardiac surgery, established renal failure or contrast nephropathy. Similarly, other studies compared diuretics with dopamine or placebo without demonstrating benefits from this drug-regimen therapy [23, 24].

Mannitol is a potent osmotic fluid, with 50 g of mannitol causing an intracellular to extra-cellular shift of 1 liter of water [25]. It is metabolically inert and mostly excreted by the kidney with a minimal reabsorption (7 %) in the renal tubule [26]. Furthermore, it is known that it has a protective role against oxidative injuries acting as a scavenger of the hydroxyl radical that may result in reducing oxidant-derived injury to the kidney, heart and lung [27, 28].

In a recent review [29], results from an international collaboration of the Critical Care Nephrology Working Group of the European Society of Intensive Care medicine (ESICM), the roles of different substances used in acute renal injury were critically evaluated and, accordingly,

recommendations for clinical practice were given. In the review, loop diuretics and mannitol were not recommended to prevent or ameliorate acute renal injury (grade 1B).

In a recent paper on mannitol use during minimally invasive partial nephrectomy, renal function outcomes were compared between patients who received i.v. Mannitol versus those who did not. Conclusions of this retrospective series were that mannitol did not influence renal function recovery and that an appropriately designed study of mannitol is needed [30].

Despite the lack of scientific evidence, our survey shows that a high proportion of surgeons both from Europe and US regularly use mannitol to protect renal function during PN and LDN (100 and 36 %, respectively); moreover, the different dosages employed at different timing during surgeries underline also the lack of standardization on its use in this setting.

Based on these findings we recently designed a prospective randomized study at our center on the use of mannitol during partial nephrectomy. All patients undergoing partial nephrectomy (open, laparoscopic or robotic) at our center will be randomly assigned to 25 g of mannitol administered as a single dose before clamping versus no mannitol. Patients will be followed postoperatively with serum creatinine, GFR and nuclear GFR at 12 h, 7 and 30 days. The study already obtained the internal ethical committee approval (IRB) and will start recruiting patients on October 15th. A second prospective randomized trial for the use of mannitol during laparoscopic live donor nephrectomy is under development.

Conclusions

Two important conclusions can be highlighted from this survey. First, the majority of the centers performing high-volume partial and live donor nephrectomy prefer to use mannitol as a kidney protector. Second, it appears that there are neither unified criteria nor standardization for mannitol indication and usage. The hope is that our ongoing prospective randomized trial will help solving the dilemma.

Appendix: Survey

Use of mannitol in partial nephrectomy and living donor nephrectomy

Please answer the questions by adding an X to the right answer

1. Institution (Name of the Institution, City, Country)
2. Type of Institution
   a. Academic
   b. Peripheral University Affiliate
   c. Public Hospital (or County Hospital)
   d. Private Hospital
   e. Other
3. Faculty number in the department

   Number
4. Number of beds of the Urology Department

   Number
5. Is mannitol (or other similar agent) used in partial or/and donor nephrectomy at your institution?
   a. Yes
   b. No

   If you answer YES, please proceed to question 7.
   If you answer NO please proceed to question 6.
6. Reason why mannitol is not available at your institution
   a. Not part of the internal protocol
   b. Do not believe in its benefits
   c. Other
7. At your institution, mannitol is used for
   a. Partial nephrectomy
   b. Living donor nephrectomy
   c. Both
8. What is the reason of using mannitol during these surgeries?
   a. Kidney protector/Antioxidan
   b. Stimulate diuresis

c. Both
d. Other

9. Who does indicate mannitol administration?

a. Urologist
b. Nephrologist
c. Anesthetist
d. Other

In case of partial nephrectomy

10. Dosage

a. 12.5 g
b. 25 g
c. Other

11. Timing

a. Before clamping
b. After clamping
c. Other

12. Other kidney protector agent

In case of living donor nephrectomy

13. Dosage

a. 12.5 g
b. 25 g
c. Other

14. Timing

a. Before clamping
b. After clamping
c. Other

15. Other kidney protector agent
16. How many partial nephrectomies are performed at your institution per year?

a. <10
b. Between 10 and 20
c. >20
d. >50
e. >100

17. How many live donor nephrectomies have you performed at your institution?

a. <10
b. Between 10 and 20
c. >20
d. >50
e. >100

Final Report on the Safety Assessment of Glycyrrhetinic Acid, Potassium Glycyrrhetinate, Disodium Succinoyl Glycyrrhetinate, Glyceryl Glycyrrhetinate, Glycyrrhetinyl Stearate, Stearyl Glycyrrhetinate, Glycyrrhizic Acid, Ammonium Glycyrrhizate, Dipotassium Glycyrrhizate, Disodium Glycyrrhizate, Trisodium Glycyrrhizate, Methyl Glycyrrhizate, and Potassium Glycyrrhizinate[1]

Glycyrrhetinic Acid and its salts and esters and Glycyrrhizic Acid and its salts and esters are cosmetic ingredients that function as flavoring agents or skin-conditioning agents—miscellaneous or both. These chemicals may be isolated from licorice plants. Glycyrrhetinc Acid is described as at least 98% pure, with 0.6% 24-OH-Glycyrrhetinic Acid, not more than 20 μg/g of heavy metals and not more than 2 μg/g of arsenic. Ammonium Glycyrrhizate has been found to be at least 98% pure and Dipotassium Glycyrrhizate has been found to be at least 95% pure. Glycyrrhetinic Acid is used in cosmetics at concentrations of up to 2%; Stearyl Glycyrrhetinate, up to 1%; Glycyrrhizic Acid, up to 0.1%; Ammonium Glycyrrhizate, up to 5%; Dipotassium Glycyrrhizate, up to 1%; and Potassium Glycyrretinate, up to 1%. Although Glycyrrhizic Acid is poorly absorbed by the intestinal tract, it may be hydrolyzed to Glycyrrhetinic Acid by a β-glucuronidase produced by intestinal bacteria. Glycyrrhetinic Acid and Glycyrrhizic Acid bind to rat and human albumin, but do not absorb well into tissues. Glycyrrhetinic Acid and Glycyrrhizic Acid and metabolites are mostly excreted in the bile, with very little excreted in urine. Dipotassium Glycyrrhizate was undetectable in the receptor chamber when tested for transepidermal permeation through pig skin. Glycyrrhizic Acid increased the dermal penetration of diclofenac sodium in rat skin. Dipotassium Glycyrrhizate increased the intestinal absorption of calcitonin in rats. In humans, Glycyrrhetinic Acid potentiated the effects of hydrocortisone in the skin. Moderate chronic or high acute exposure to Glycyrrhizic Acid, Ammonium Glycyrrhizate, and their metabolites have been demonstrated to cause transient systemic alterations, including increased potassium excretion, sodium and water retention, body weight gain, alkalosis, suppression of the renin-angiotensis-aldosterone system, hypertension, and muscular paralysis; possibly through inhibition of 11β-hydroxysteroid dehydrogenase-2 (11β-OHSD2) in the kidney. Glycyrrhetinic Acid and its derivatives block gap junction intracellular communication in a dose-dependent manner in animal and human cells, including epithelial cells, fibroblasts, osteoblasts, hepatocytes, and astrocytes; at high concentrations, it is cytotoxic. Glycyrrhetinic Acid and Glycyrrhizic Acid protect liver tissue from carbon tetrachloride. Glycyrrhizic Acid has been used to treat chronic hepatitis, inhibiting the penetration of the hepatitis A virus into hepatocytes. Glycyrrhetinic Acid and Glycyrrhizic Acid have anti-inflammatory effects in rats and mice. The acute intraperitoneal LD_{50} for Glycyrrhetinic Acid in mice was 308 mg/kg and the oral LD_{50} was >610 mg/kg. The oral LD_{50} in rats was reported to be 610 mg/kg. Higher LD_{50} values were generally reported for salts. Little short-term, subchronic, or chronic toxicity was seen in rats given ammonium, dipotassium, or disodium salts of Glycyrrhizic Acid. Glycyrrhetinic Acid was not irritating to shaved rabbit skin, but was considered slightly irritating in an in vitro test. Glycyrrhetinic Acid inhibited the mutagenic activity of benzo[a]pyrene and inhibited tumor initiation and promotion by other agents in mice. Glycyrrhizic Acid inhibited tumor initiation by another agent, but did not prevent tumor promotion in mice. Glycyrrhizic Acid delayed mortality in mice injected with Erlich ascites tumor cells, but did not reduce the mortality rate. Ammonium Glycyrrhizate was not genotoxic in in vivo and in vitro cytogenetics assays, the dominant lethal assay, an Ames assay, and heritable translocation tests, except for possible increase in dominant lethal mutations in rats given 2000 mg/kg day^{-1} in their diet. Disodium Glycyrrhizate was not carcinogenic in mice in a drinking water study at exposure levels up to 12.2 mg/kg day^{-1} for 96 weeks. Glycyrrhizate salts produced no reproductive or developmental toxicity in rats, mice, golden hamsters, or Dutch-belted rabbits, except for a dose-dependent increase (at 238.8 and 679.9 mg/kg day^{-1}) in sternebral variants in a study using rats. Sedation, hypnosis, hypothermia, and respiratory depression were seen in mice given 1250 mg/kg Glycyrrhetinic Acid intraperitoneally. Rats fed a powdered diet containing up to 4% Ammonium Glycyrrhizate had no treatment related effects in motor function tests, but active avoidance was facilitated at 4%, unaffected at 3%, and depressed at 2%. In a study of 39 healthy volunteers, a no effect level of 2 mg/kg/day was determined for Glycyrrhizic Acid given orally for 8 weeks. Clinical tests in seven normal individuals given oral Ammonium Glycyrrhizate at 6 g/day for 3 days revealed reduced renal and thermal sweat excretion of Na^+ and K^+, but carbohydrate and protein metabolism were not affected. Glycyrrhetinic Acid at concentrations up to 6% was not a skin irritant or a sensitizer in clinical tests. Neither Glycyrrhizic Acid, Ammonium Glycyrrhizate,

Received 30 November 2006; accepted 5 March 2007.
[1]Reviewed by the Cosmetic Ingredient Review Expert Panel. Address correspondence to F. Alan Andersen, Cosmetic Ingredient Review, 1101 17th Street, NW, Suite 412, Washington, DC 20036, USA.

nor Dipotassium Glycyrrhizate at 5% were phototoxic agents or photosensitizers. Birth weight and maternal blood pressure were unrelated to the level of consumption of Glycyrrhizic Acid in 1049 Finnish women with infants, but babies whose mother consumed >500 mg/wk were more likely to be born before 38 weeks. The Cosmetic Ingredient Review (CIR) Expert Panel noted that the ingredients in this safety assessment are not plant extracts, powders, or juices, but rather are specific chemical species that may be isolated from the licorice plant. Because these chemicals may be isolated from plant sources, however, steps should be taken to assure that pesticide and toxic metal residues are below acceptable levels. The Panel advised the industry that total polychlorobiphenyl (PCB)/pesticide contamination should be limited to not more than 40 ppm, with not more than 10 ppm for any specific residue, and that toxic metal levels must not contain more than 3 mg/kg of arsenic (as As), not more than 0.002% heavy metals, and not more than 1 mg/kg of lead (as Pb). Although the Panel noted that Glycyrrhizic Acid is cytotoxic at high doses and ingestion can have physiological effects, there is little acute, short-term, subchronic, or chronic toxicity and it is expected that these ingredients would be poorly absorbed through the skin. These ingredients are not considered to be irritants, sensitizers, phototoxic agents, or photosensitizers at the current maximum concentration of use. Accordingly, the CIR Expert Panel concluded that these ingredients are safe in the current practices of use and concentration. The Panel recognizes that certain ingredients in this group are reportedly used in a given product category, but the concentration of use is not available. For other ingredients in this group, information regarding use concentration for specific product categories is provided, but the number of such products is not known. In still other cases, an ingredient is not in current use, but may be used in the future. Although there are gaps in knowledge about product use, the overall information available on the types of products in which these ingredients are used and at what concentration indicate a pattern of use. Within this overall pattern of use, the Expert Panel considers all ingredients in this group to be safe.

INTRODUCTION

Glycyrrhetinic Acid, its salts and esters, and Glycyrrhizic Acid, and its salts and esters are used as cosmetic ingredients. This review presents information relevant to the safety of these ingredients as considered by the Cosmetic Ingredient Review (CIR) Expert Panel.

These ingredients are not plant extracts, powders, or juices, but rather are specific chemical species that may be isolated from the licorice plant. Plant-derived extracts, powders, juices, etc. [e.g., Glycyrrhiza Glabra (Licorice) Leaf Extract] also used as cosmetic ingredients, which may contain these organic compounds, but likely will include other chemicals, will be reviewed in another report.

The ingredients in this safety assessment are:

- Glycyrrhetinic Acid,
- Potassium Glycyrrhetinate,
- Disodium Succinoyl Glycyrrhetinate,
- Glyceryl Glycyrrhetinate,
- Glycyrrhetinyl Stearate,
- Stearyl Glycyrrhetinate,
- Glycyrrhizic Acid,
- Ammonium Glycyrrhizate,
- Dipotassium Glycyrrhizate,
- Disodium Glycyrrhizate,
- Trisodium Glycyrrhizate,
- Methyl Glycyrrhizate, and
- Potassium Glycyrrhizinate.

This review presents information relevant to the safety of these cosmetic ingredients as considered by the CIR Expert Panel.

No published information was identified for Disodium Succinoyl Glycyrrhetinate, Glyceryl Glycyrrhetinate, Glycyrrhetinyl Stearate, Methyl Glycyrrhizate, Potassium Glycyrrhetinate, Potassium Glycyrrhizinate, or Trisodium Glycyrrhizate, but they are considered to be sufficiently structurally related to the rest of the ingredients that the data may be extrapolated to address their safety.

CHEMISTRY

Definition and Structure

Glycyrrhetinic Acid (CAS no. 471-53-4) is an organic compound derived from Glycyrrhizic Acid or shredded licorice roots. It conforms generally to the structure presented in Figure 1 (Gottschalck and McEwen 2004).

Synonyms for Glycyrrhetinic Acid include Glycyrrhetic Acid; Olean-12-En-29-Oic-Acid, 3-Hydroxy-11-Oxo-, (3β, 20β)-; and (3β, 20β)-3-Hydroxy-11-Oxo- Olean-12-En-29-Oic-Acid. All 13 ingredients reviewed in this report have in common the basic core structure of Glycyrrhetinic Acid (Gottschalck and McEwen 2004). There are two stereoisomers of Glycyrrhetinic Acid described in the literature, 18α- and 18β-Glycyrrhetinic Acid. It is unclear which stereoisomer is used in cosmetics or if it is a mixture.

Glycyrrhetinic Acid has the empirical formula of $C_{30}H_{46}O_4$ and conforms to the formula presented in Figure 1, with both R_1 and R_2 being OH. Table 1 lists its derivatives and the R groups corresponding to each one.

Potassium Glycyrrhetinate (CAS no. 85985-61-1) is the potassium salt of Glycyrrhetinic Acid. Potassium Glycyrrhetinate is also known as Olean-12-En-29-Oic Acid, 3-Hydroxy-1, 1-Oxo-, Monopotassium Salt (Gottschalck and McEwen 2004).

Disodium Succinoyl Glycyrrhetinate (no CAS no. listed) is the disodium salt of the ester of succinic alcohol and Glycyrrhetinic Acid that conforms to the structure shown in Figure 1, with R groups given in Table 1 (Gottschalck and McEwen 2004).

Glyceryl Glycyrrhetinate (CAS no. 108916-85-4) is the monoester of glycerine and Glycyrrhetinic Acid. Synonyms for Glyceryl Glycyrrhetinate include Glycyrrhetinic Acid, Glyceryl Ester; Glyceryl Glycyrrhetate; and Olean-12-En-29-Oic Acid, 3-Hydroxy-11-Oxo-, Monoester with 1,2,3 Propanetriol, (3β, 20β) (Gottschalck and McEwen 2004).

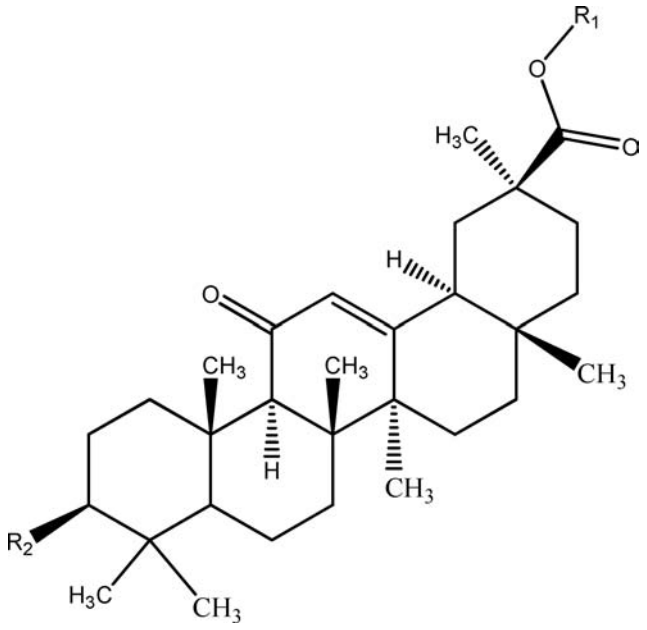

FIGURE 1
Glycyrrhetinic Acid. R_1 and R_2 are OH groups (Gottschalck and McEwen 2004).

Glycyrrhetinyl Stearate (CAS no. 4827-59-2) is the stearic acid ester of Glycyrrhetinic Acid that conforms generally to the structure displayed in Figure 1, with R groups given in Table 1. It is also known as 3-Stearoyloxy Glycyrrhetinic Acid (Gottschalck and McEwen 2004).

Stearyl Glycyrrhetinate (CAS no. 13832-70-7) is the ester of stearyl alcohol and Glycyrrhetinic Acid which conforms to the structure displayed in Figure 1, with R groups given in Table 1. Synonyms include Octadecyl Glycyrrhetinate; Octadecyl 3-Hydroxy-11-Oxoolean-12-En-29-Oate; and Olean-12-En-29-Oic Acid, 3-Hydroxy-11-Oxo-, Octadecyl Ester (Gottschalck and McEwen 2004).

Glycyrrhizic Acid (CAS no. 1405-86-3) is a natural material extracted from the plant *Glycyrrhiza Glabra* (Gottschalck and McEwen 2004). Glycyrrhizic Acid is a conjugate of Glycyrrhetinic Acid and two molecules of glucuronic acid. It conforms generally to the structure in Figure 1, with R groups given in Table 1. Glycyrrhizic Acid is also known as (3β, 20β)-20-Carboxy-11-Oxo-30-Norlean-12-En-3-Yl-2-*O*-β-17-Glucopyranuronosyl-α-D-Glucopyranosiduronic Acid; α-D-Glucopyranosiduronic Acid, (3β, 20β)-20-Carboxy-11-Oxo-30-Norlean-12-En-3-Yl-2-*O*-β-17-Glucopyranuronosyl-; Glycyrrhetinic Acid Glycoside; Glycyrrhizin; and Glycyrrhizinic Acid (Gottschalck and McEwen 2004).

Ammonium Glycyrrhizate (CAS no. 53956-04-0) is the ammonium salt of Glycyrrhizic Acid (q.v.). Synonyms include Ammonium Glycyrrhizinate; α-D-Glucopyranosiduronic Acid, (3β, 20β)-20-Carboxy-11-Oxo-30-Norlean-12-En-3-Yl-2-*O*-β-D-Glucopyranuronosyl-, Ammoniate; Glycyrrhizin Ammonium Salt; Glycyrrhizic Acid Ammonium Salt; Monoammonium Glycyrrhizinate; and Monoammonium α-Glycyrrhizinate (Gottschalck and McEwen 2004).

Dipotassium Glycyrrhizate (CAS no. 68797-35-3) is the dipotassium salt of Glycyrrhizic Acid (q.v.). Synonyms for Dipotassium Glycyrrhizate include Dipotassium Glycyrrhizinate; α-D-Glucopyranosiduronic Acid, (3β, 20β)-20-Carboxy-11-Oxo-30-Norlean-12-En-3-Yl-2-*O*-β-D-Glucopyranuronosyl-, Dipotassium Salt; and 30-Noroleanane, α-D-Glucopyranosiduronic Acid Derivative (Gottschalck and McEwen 2004).

Disodium Glycyrrhizate (CAS no. 71277-79-7) is the disodium salt of Glycyrrhizic Acid. Synonyms for Disodium Glycyrrhizate include Disodium Glycyrrhizinate; α-D-Glucopyranosiduronic Acid, (3β, 20β)-20-Carboxy-11-Oxo-30-Norlean-12-En-3-Yl-2-*O*-β-D-Glucopyranuronosyl-, Disodium Salt; and 30-Noroleanane, α-D-Glucopyranosiduronic Acid Derivative (Gottschalck and McEwen 2004).

Trisodium Glycyrrhizate (no CAS no. available) is the trisodium salt of Glycyrrhizic Acid (q.v.) (Gottschalck and McEwen 2004).

Methyl Glycyrrhizate (no CAS no. available) is the ester of methyl alcohol and Glycyrrhizic Acid (q.v.). It is also known

TABLE 1
R groups in Figure 1 for derivatives of Glycyrrhetinic Acid (Gottschalck and McEwen 2004).

Compound	R_1	R_2
Potassium Glycyrrhetinate	K	OH
Disodium Succinoyl Glycyrrhetinate	Na	O-C(O)-CH_2-CH_2-C(O)-ONa
Glyceryl Glycyrrhetinate	CH_2-CH(OH)-CH_3	OH
Glycyrrhetinyl Stearate	H	O-C(O)-$(CH_2)_{17}$-CH_3
Stearyl Glycyrrhetinate	$(CH_2)_{17}$-CH_3	OH
Glycyrrhizic Acid	H	(β-Glucuronylglucuronic acid)
Ammonium Glycyrrhizate	NH_3	(β-Glucuronylglucuronic acid)
Dipotassium Glycyrrhizate	K	(β-Glucuronylglucuronic acid·K)
Disodium Glycyrrhizate	Na	(β-Glucuronylglucuronic acid·Na)
Methyl Glycyrrhizate	CH_3	(β-Glucuronylglucuronic acid)

TABLE 2
Physical and chemical properties of Glycyrrhetinic Acid and Glycyrrhizic Acid and their derivatives (Lide 1993; CTFA 2004; Cognis 2002).

Compound	Molecular Weight	Boiling point	Melting point	Soluble in:	UV absorbance hrulefill Max.	UV absorbance hrulefill $E^{1\%}_{1cm}$

as Glycyrrhizic Acid, Methyl Ester (Gottschalck and McEwen 2004).

Potassium Glycyrrhizinate is an enzymatically produced mixture of potassium salts of Glycyrrhizic Acid (q.v.) and Glycyrrhetinic Acid monoglycoside. It is also known as Glycopyranosiduronic Acid, 20-Carboxy-11-Oxo-30-Norolean-12-En-3-Ly and 2-Glycopyranuronosyl-, Potassium Salt (Gottschalck and McEwen 2004).

Physical and Chemical Properties

The physical and chemical properties of Glycyrrhetinic Acid and Glycyrrhizic Acid are summarized in Table 2. Data were not available for the other ingredients.

Method of Manufacture

Glycyrrhetinic Acid is derived from Glycyrrhizic Acid or isolated from shredded licorice roots (Gottschalck and McEwen 2004). 18β-Glycyrrhetinic Acid is obtained from the licorice root (*Glycyrrhiza glabra L.*) by hydroalcoholic extraction, hydrolysis and crystallization methods (CTFA 2004).

Glycyrrhizin (Glycyrrhizic Acid) and Ammonium Glycyrrhizate are isolated from water-soluble extracts from the dried rhizome and roots of *Glycyrrhiza glabra* or of other *Glycyrrhiza* species yielding a yellow and sweet wood (Informatics, Inc. 1972). Glycyrrhizin and Ammonium Glycyrrhizate may also be isolated from extracts of the roots of *Abrus precatorius*, *Periandra dulcis*, *Periandra mediteranea*, and from the bark of the trees *Lucuma glycophylla*, *Achras sapota*, and *Sideroxylon richarhii* (Informatics, Inc. 1972).

Ammoniated Glycyrrhizin (also known as Ammonium Glycyrrhizate) is prepared from the water extract of licorice root by acid precipitation followed by neutralization with dilute ammonia (21CFR148.1408). It is also reported that Ammonium Glycyrrhizate is obtained from the licorice root (*Glycyrrhiza glabra L.*) by hydroalcoholic extraction, hydrolysis and crystallization methods (CTFA 2004).

Dipotassium Glycyrrhizate is obtained from the licorice root (*Glycyrrhiza glabra L.*) by hydroalcoholic extraction, hydrolysis and crystallization methods (CTFA 2004).

Analytical Methods

Spinks and Fenwick (1990) used high-performance liquid chromatography (HPLC) to determine the content of Glycyrrhizic Acid in licorice-containing confectionary and health products. Okamura et al. (2001) used semi-micro-HPLC to simultaneously detect Glycyrrhizic Acid, Glycyrrhetinic Acid, and glycyrrhetinic acid mono-glucuronide in a combination of licorice root and peony root with rat feces. Liu et al. (2001) used mass spectrometry and nuclear magnetic resonance spectra to isolate and identify Glycyrrhizic Acid, Glycyrrhetinic Acid, and other constituents in a licorice extract.

Impurities

Cognis (2002) reports that its products Plantactiv® GLA18 (Glycyrrhetinic Acid), Plantactiv® AGL (Ammonium Glycyrrhizate), and Plantactiv® PGL (Dipotassium Glycyrrhizate) are a minimum 98%, 98%, and 95% pure, respectively.

Maruzen Pharaceuticals Company, Ltd. (2004) analyzed Glycyrrhetinic Acid. They found 99.4% 18β-Glycyrrhetinic Acid and 0.6% 24-OH-Glycyrrhetinic Acid by the HPLC method. They also found not more than 20 μg/g of heavy metals and not more than 2 μg/g of arsenic. Hill Laboratories (2004) conducted a multiresidue Pesticide Analysis on Glycyrrhetic Acid. There was no residue detected by ethyl acetate extraction, gel permeation chromatography cleanup, gas chromatography-electron capture detector/nitrogen phosphorus detector, and gas chromatography–mass spectrometry (GC-MS).

Cognis reports that Dipotassium Glycyrrhizate, 18β-Glycyrrhetinic Acid, and Ammonium Glycyrrhizate samples are absent of allergens except for *d*-Limonene at <1 ppm (CTFA 2004).

USE

Cosmetic Use

As given in the *International Cosmetic Ingredient Dictionary and Handbook*, **Glycyrrhetinic Acid** is a skin conditioning agent-miscellaneous (Gottschalck and McEwen 2004) and is reportedly used in 65 cosmetic formulations (FDA 2002) at a maximum reported concentration of use of 2% (CTFA 2003).

The frequencies of use and use concentrations of Glycyrrhetinic Acid in specific product categories are listed in Table 3.

Potassium Glycyrrhetinate functions as a flavoring agent and skin-conditioning agent—miscellaneous in cosmetic products (Gottschalck and McEwen 2004). However, there were no reports to FDA (2002) of its use in any cosmetic product categories and no concentration of use data were available.

Disodium Succinoyl Glycyrrhetinate is used in four permanent wave products (FDA 2002) as shown in Table 3. No concentration of use data were available for this compound. The function of this ingredient is not given in the *International Cosmetic Ingredient Dictionary and Handbook* (Gottschalck and McEwen 2004).

Glyceryl Glycyrrhetinate functions as a flavoring agent in cosmetic products (Gottschalck and McEwen 2004). However, there were no reports to FDA (2002) of its use in any cosmetic product categories and no concentration of use data were available.

Glycyrrhetinyl Stearate functions as a flavoring agent in cosmetic products (Gottschalck and McEwen 2004). However, there were no reports to FDA (2002) of its use in any cosmetic product categories and no concentration of use data were available.

Stearyl Glycyrrhetinate functions in cosmetics as a flavoring agent (Gottschalck and McEwen 2004) and is reportedly used in 35 cosmetic products (FDA 2002) at use concentrations up to 0.1% (CTFA 2003) as shown in Table 3.

Glycyrrhizic Acid functions as a flavoring agent and skin-conditioning agent—miscellaneous (Gottschalck and McEwen 2004). The use of Glycyrrhizic Acid in specific product categories (FDA 2002) are listed in Table 3. Glycyrrhizic Acid is reportedly used at 0.1% in many cosmetic product categories (CTFA 2003).

Ammonium Glycyrrhizate is a flavoring agent and skin-conditioning agent—miscellaneous (Gottschalck and McEwen 2004) and is used in 72 cosmetic formulations (FDA 2002) at a maximum concentration of use of 5% (CTFA 2003) as shown in Table 3.

Dipotassium Glycyrrhizate functions as a flavoring agent and skin-conditioning agent—miscellaneous (Gottschalck and McEwen 2004) and is used in 29 cosmetic formulations (FDA 2002) at a maximum concentration of 1% (CTFA 2003). The frequencies of use and use concentrations of Dipotassium Glycyrrhizate in specific product categories are listed in Table 3.

Disodium Glycyrrhizate is a flavoring agent and skin-conditioning agent—miscellaneous in cosmetic products (Gottschalck and McEwen 2004). However, there were no reports to FDA (2002) of its use in any cosmetic product categories. No concentration of use data were available.

Trisodium Glycyrrhizate is a flavoring agent and skin-conditioning agent—miscellaneous (Gottschalck and McEwen 2004). FDA (2002) reports that it is used in one hair conditioner and in one other noncoloring hair preparation as shown in Table 3. No concentration of use data were available.

Methyl Glycyrrhizate is a flavoring agent in cosmetic products (Gottschalck and McEwen 2004). However, there were no reports to FDA (2002) of its use in any cosmetic product categories. No concentration of use data were available.

Potassium Glycyrrhizinate is a skin-conditioning agent—miscellaneous in cosmetic products (Gottschalck and McEwen 2004). Although there were no reports to FDA (2002) of its use in any cosmetic product categories, a concentration of use of 1.0% was given in an industry survey and is shown in Table 3 (CTFA 2003).

Noncosmetic Use

Bombardelli (1991) demonstrated that 18β-Glycyrrhetinic Acid can be used as a vehicle to increase the transdermal absorption of some topical medications.

Although licorice and licorice derivatives are generally recognized as safe (GRAS) as food ingredients, the Food and Drug Administration (FDA) has established the following maximum restrictions on the levels of Glycyrrhizic Acid in certain types of foods: 0.05% in baked goods; 0.1% in alcoholic beverages; 0.15% in nonalcoholic beverages; 1.1% in chewing gum; 16.0% in hard candy; 0.15% in herbs and seasonings and in plant protein products; 3.1% in soft candy; 0.5% in vitamins and dietary supplements; and 0.1% in all other food except sugar substitutes. Glycyrrhizic Acid may not be used as a non-nutritive sweetener in sugar substitutes (12CFR184.1408).

Touitou et al. (1988) described the use of a Glycyrrhizic Acid gel as a vehicle for an idoxuridine topical preparation. The Glycyrrhizic Acid gel facilitated the idoxuridine absorption through hairless mouse skin.

Glycyrrhizic Acid is used in the treatment of chronic hepatitis B and C (Chitturi and Farrell 2001).

The GRAS status of Ammonium Glycyrrhizate was supported by a review performed by the Life Science Research Office (LSRO 1974).

Dipotassium Glycyrrhizate is an anti-inflammatory agent that is used to treat chronic dermatitis (Trotta et al. 2002).

ABSORPTION, DISTRIBUTION, METABOLISM, AND EXCRETION

Overview

Ploeger et al. (2001a) published an extensive review of the pharmacokinetics of Glycyrrhizic Acid in rodents and humans. Glycyrrhizic Acid is poorly absorbed by the gastrointestinal tract. However, Glycyrrhizic Acid is hydrolyzed by a specialized β-glucuronidase produced by intestinal bacteria to make Glycyrrhetinic Acid. The plasma of germ-free rats showed no Glycyrrhetinic Acid after oral administration of Glycyrrhizic Acid. After hydrolysis by bacteria, Glycyrrhetinic Acid is then absorbed into the circulatory system. However, this absorption is saturable at doses above 25 mg/kg in both rats

and humans. Both Glycyrrhetinic Acid and Glycyrrhizic Acid bind extensively to rat and human plasma albumin.

This binding is saturable at high plasma concentrations. These compounds do not absorb well into tissues, as the tissue-to-blood partition coefficients for all rat tissues tested are less than 1.

Hepatic metabolism of Glycyrrhetinic Acid produces the conjugates 18-β-glycyrrhetyl-3-*O*-monoglucuronide, 18-β-glycyrrhetyl-3-*O*-hydrogen sulfate, and 18-β-glycyrrhetyl-3-*O*-monoglucuronide. Glycyrrhetinic Acid and Glycyrrhizic Acid and metabolites are mostly excreted in the bile. Once in the gastrointestinal tract, bacterial enzymes can remove the glucuronide and sulfate conjugates to restore absorbable Glycyrrhetinic Acid. Thus, Glycyrrhetinic Acid and its metabolites are subject to enterohepatic cycling in rats and, presumably, in humans. Very little is excreted in the urine (Ploeger et al. 2001a).

Imai et al. (1999) used in vivo (Sprague-Dawley rats) and in vitro (Caco-2 cells) models to evaluate the enhancing effects of Dipotassium Glycyrrizate on the intestinal absorption of drugs. The authors found that it is not Dipotassium Glycyrrizate but its metabolite Glycyrrhetinic Acid that enhances drug absorption in the intestine. Salmon calcitonin was the drug used to demonstrate this effect.

Trotta et al. (2002) studied the ability of elastic liposomes to increase the transepidermal permeation of Dipotassium Glycyrrhizate through pig skin. Full-thickness pig ear skin was prepared and fixed in a Franz-type apparatus for the measurement of transdermal permeation. The diffusion area was 2.05 cm^2, and the receptor chamber was filled with 6 ml of 0.002% aqueous sodium azide. The application side was dry when 100 μg of test material was applied. The test materials were 0.25% Dipotassium Glycyrrhizate in water solution, 1% Dipotassium Glycyrrhizate in a water micelle solution, liposomes of soya lethicin or hydrogenated soya lethicin each with 0.25% Dipotassium Glycyrrhizate, or oil/water emulsions containing 0.25% Dipotassium Glycyrrhizate. Test material was left on the skin surface for 12 h, and samples of fluid from the receptor chamber were collected at regular intervals for ultraviolet (UV)-HPLC analysis. All treatments showed negligible flux of Dipotassium Glycyrrhizate across the pig skin, as concentrations of Dipotassium Glycyrrhizate in the receptor chamber fluid were below the UV-HPLC detection limit.

After the 12-h treatment period, the treatment surface was washed five times with 50% ethanol and then water. The skin was removed from the apparatus and homogenized, and the Dipotassium Glycyrrhizate content of the skin was determined by HPLC. Dipotassium Glycyrrhizate was found in the skin at 12 ± 3 $\mu g/cm^2$ from the 0.25% water solution, 19 ± 5 $\mu g/cm^2$ from the 1% water micelle solution, and 13 ± 4 $\mu g/cm^2$ from the 0.25% oil/water emulsion. The liposomes containing 0.25% Dipotassium Glycyrrhizate increased the skin content from 62 $\pm$ 8 to 71 $\pm$10 $\mu g/cm^2$, approximately four to five times the amount absorbed without liposomes. Thus, although Dipotassium Glycyrrhizate was able to enter the pig skin, it was unable to permeate through all layers of the skin tissue (Trotta et al. 2002).

Animal

Parke et al. (1963) treated six albino rats with a single oral dose of 60 mg/kg of tritium-labeled β-Glycyrrhetinic Acid in aqueous suspension. Two additional rats received a single subdermal injection of 60 mg/kg tritium-labeled β-Glycyrrhetinic Acid in aqueous suspension. Blood, urine, and feces were collected for several time points after the dose was given. Detection of Glycyrrhetinic Acid and its metabolites in the biological samples was accomplished by paper chromatography using different media and scintillation counting of radioactivity.

In rats receiving 60 mg/kg orally, an average of 86% of the radioactivity administered was recovered in 1 to 3 days with 83% in the feces, 1% in the urine, and 4% remained in the liver. In rats given 60 mg/kg subdermally, 74% of the administered radioactivity was recovered with 73% in the feces and 1% in the urine. Of the radioactivity recovered in the feces, 7.4% was unchanged β-Glycyrrhetinic Acid in the orally dosed rats, and 5.2% in subdermally dosed rats. The remaining radioactivity in the feces was attributed to α-Glycyrrhetinic Acid, 3-keto- β-glycyrrhetinic acid, 3-aceto- β-glycyrrhetinic acid, Ammonium Glycyrrhizate, and other metabolites (Parke et al. 1963).

Ishida et al. (1989) investigated the pharmacokinetics of Glycyrrhetinic Acid. Male Wistar rats were given a bolus intravenous injection of 2, 5, or 12 mg/kg Glycyrrhetinic Acid. The sample size per group was not reported. Samples of blood, bile, and lymph were collected by cannulae. The investigators found that Glycyrrhetinic Acid in rats adhered to a two-compartment pharmacokinetic model.

The first-order partition rate from the central compartment to the peripheral compartment was 0.0797 min^{-1}, and from the peripheral back to the central compartment was 0.0817 min^{-1}. The volume of distribution of the central compartment was 72.293 ml/kg. The Michaelis constant and maximum velocity of elimination from the central compartment were 27.970 μg/ml and 15.329 μg/ml/min/kg, respectively. The plasma-to-blood concentration ratio was constant at all doses (1.787), indicating that Glycyrrhetinic Acid was not well absorbed into erythrocytes. Tissue-to-plasma concentration ratios were all less than 1 (maximum was 0.121 in kidney), indicating poor tissue distribution. The tissue-to-plasma concentration ratio of skin was 0.089 ± 0.006. The steady state volume of distribution was statistically similar among the three dose groups. However, the total body clearance decreased in a dose-dependent manner with increasing doses: 8.194, 6.047, and 3.694 ml/min/kg for the 2, 5, and 12 mg/kg groups, respectively. The authors concluded that the elimination of Glycyrrhetinic Acid was saturable (Ishida et al. 1989).

Cantelli-Forti et al. (1997) studied the biliary excretion of Glycyrrhizic Acid and Glycyrrhetinic Acid after oral or intravenous administration of licorice extract or Glycyrrhizic Acid. Male Sprague-Dawley rats received 480 mg/kg Glycyrrhizic

Acid or 6278 mg/kg licorice extract by oral gavage ($n = 6$ rats per treatment group). The Glycyrrhizic Acid dose was selected to give the same amount of Glycyrrhizic Acid found in the licorice extract dose. Six control rats were given 10 ml/kg distilled water. After dosing, animals were anesthetized, and their abdomens were opened. The common bile duct of each animal was tied and cannulated with a polyethylene catheter, through which bile was steadily collected every 120 min for 16 h.

Bile samples were analyzed by HPLC to detect Glycyrrhizic Acid and Glycyrrhetinic Acid. After oral gavage of Glycyrrhizic Acid, the excretion of Glycyrrhizic Acid via bile peaked (18.02 μg/min·kg) at 8 to 10 h and then decreased sharply. After oral gavage with licorice extract (containing the same amount of Glycyrrhizic Acid), the biliary excretion of Glycyrrhizic Acid was significantly reduced and peaked (3.43 μg/min·kg) at 6 to 8 h. Area under the curve analysis indicated a significant sevenfold increase in biliary excretion of Glycyrrhizic Acid after oral Glycyrrhizic Acid, compared to licorice extract. Thus, excretion of Glycyrrhizic Acid is greater after oral Glycyrrhizic Acid than oral licorice extract. Levels of Glycyrrhetinic Acid in the bile were below the detection limits in all bile samples.

In another experiment, rats were anesthetized and their bile ducts were cannulated for bile collection. Baseline bile was collected for 1 h and then 32.7 mg/kg licorice extract or 2.5 mg/kg Glycyrrhizic Acid was injected intravenously over a period of 1 h by means of a peristaltic pump. The Glycyrrhizic Acid dose was selected to give the same amount of Glycyrrhizic Acid found in the licorice extract dose. Bile samples were collected hourly for 6 h. After intravenous administration of Glycyrrhizic Acid, bile flow was increased after extract injection, compared to Glycyrrhizic Acid injection. The authors did not compare the biliary Glycyrrhizic Acid concentrations after intravenous injection of licorice extract and Glycyrrhizic Acid (Cantelli-Forti et al. 1997).

Ichikawa et al. (1986) demonstrated that Glycyrrhizic Acid is excreted in the bile and undergoes enterohepatic cycling in rats. One group of rats was surgically fitted with biliary fistulas, whereas control rats were left intact. The rats received a single intravenous dose of 100 mg/kg Glycyrrhizic Acid. Plasma concentrations of Glycyrrhizic Acid were measured from blood samples taken at several time points after the dose was given. Plasma decay in control rats was biphasic. The area under the curve (AUC) of plasma concentrations for 12 h after dosing was significantly increased ($p < 0.01$) in control rats than in rats with biliary fistulization. Total body clearance of Glycyrrhizic Acid was 0.372 ml/min/kg in control rats and 0.936 ml/min/kg in rats with biliary fistulization, a significant difference ($p < 0.01$). The total cumulative excretion of Glycyrrhizic Acid in rats for 48 h was as follows: 80.6% of administered dose in bile in both control and fistulated rats; 9.8% in urine of control rats and 4.5% in urine of rats with bile fistulas; 5.5% in feces of control rats; and no Glycyrrhizic Acid was detected in the feces of rats with bile fistulas. These findings were attributed to the elimination of Glycyrrhizic Acid primarily in the bile.

Ishida et al. (1992) studied the pharmacokinetics of Glycyrrhizic Acid in rats. Male Wistar rats received 5, 10, 20, or 50 mg/kg Glycyrrhizic Acid via intravenous administration in the femoral vein. Sample size per group was not reported. Blood, bile, and urine were collected by cannulae at several time points up to 48 h. The decrease in mean plasma concentration was biphasic.

The steady-state volume of distribution (Vd_{ss}) for the 20 and 50 mg/kg groups (86.4 and 115.0 ml/kg, respectively) was significantly higher ($p < 0.05$) than in the 5 and 10 mg/kg groups (58.2 and 59.8 ml/kg, respectively). Total body clearance (Cl_{tot}) for the 20 and 50 mg/kg groups (1.54 and 1.20 ml/min/kg, respectively) was significantly lower ($p < 0.05$) than in the 5 and 10 mg/kg groups (1.91 and 1.98 ml/min/kg, respectively). Biliary excretion for 8 h after dosing was similar between all dose levels, ranging from 85.9% to 95.7% of the administered dose, suggesting a high potential of enterohepatic cycling. Calculations of plasma protein concentration and binding suggested that plasma protein binding may play a role in the changes in pharmacokinetic parameters at different dose levels (Ishida et al. 1992).

Yamamura et al. (1995) compared the phamacokinetic behavior of Glycyrrhizic Acid as a function of route of administration. Male Wistar rats were exposed to 2, 10, or 50 mg/kg Glycyrrhizic Acid either by intravenous (i.v.), intraperitoneal (i.p.), or oral (p.o.) routes. The number of rats per group was not reported. Cannulae were surgically placed and used to collect blood from the femoral artery and urine from the bladder. Blood and urine were collected at regular intervals before and after dosing.

After each i.v. administration, the Glycyrrhizic Acid plasma concentration decreased biexponentially, resulting in a biological half-life of 2.1 to 2.7 h. The steady-state volume of distribution was 98.6 to 166.0 ml/kg [p = n.s. (nonsignificant) between doses], and the total body clearance was 77.3 to 93.0 ml/h·kg (p = n.s. between doses). Urinary excretion of Glycyrrhizic Acid over the 24 h after 2, 10, and 50 mg/kg amounted to 1.3%, 1.9%, and 3.2% of the administered dose, respectively. The metabolite Glycyrrhetinic Acid appeared in the urine at 0.03%, 0.04%, and 0.01% of the administered dose of Glycyrrhizic Acid, respectively, to the above doses.

After i.p. injection, Glycyrrhizic Acid appeared rapidly in the plasma and reached maximum concentration within 30 min. The mean maximum concentration for the 2, 10, and 50 mg/kg dose groups was 4.7, 33.0, and 238.9 μg/ml, respectively. The biological half-life ranged from 2.5 to 2.9 h. The respective apparent clearance values for the three doses were 137.3, 108.62, and 85.6 ml/kg·h.

Rats receiving 2 or 10 mg/kg doses orally had Glycyrrhizic Acid plasma concentrations of 0.2 or 0.4 μg/ml, respectively. Glycyrrhizic Acid was eliminated by 2 h after dosing, whereas, it was detected at a concentration of 1.3 μg/ml in rats of the 50 mg/kg p.o. group, and Glycyrrhizic Acid remained in the plasma for over 8 h.

These investigators also studied the intestinal absorption of Glycyrrhizic Acid in an in situ experiment. A closed intestinal

loop of ileum was prepared, and the mesenteric vein was cannulated. A dose of 10 or 50 mg/kg Glycyrrhizic Acid was injected into the ileum, and mesenteric blood was collected for up to 100 min. Only 1.2% of the 10 mg/kg dose and 1.9% of the 50 mg/kg dose was absorbed as Glycyrrhizic Acid by the ileum. From 0.2% to 0.4% of the administered dose was collected in the blood as Glycyrrhetinic Acid. The intestinal contents contained 4.8% of the administered dose as Glycyrrhizic Acid. Two unspecified metabolites of Glycyrrhizic Acid were in the intestinal contents, amounting to 83.8% and 0.45% of the administered dose. Glycyrrhetinic Acid was not detected in the intestinal contents. In another experiment, Glycyrrhizic Acid was stable in gastric juices at 37°C and pH 1.4 for 3 h.

In summary, the pharmacokinetic profiles of i.v.- and i.p.-administered Glycyrrhizic Acid were similar, whereas the oral route had low bioavailability, possibly due to poor absorption from the intestinal tract (Yamamura et al. 1995).

Imai et al. (1999) and Akao (1994, 1997) demonstrated that Dipotassium Glycyrrhizate and Glycyrrhizic Acid, respectively, are metabolized by intestinal microflora into Glycyrrhetinic Acid before absorption can occur.

Wang et al. (1994) found that, in rats, Glycyrrhizic Acid is hydrolyzed to Glycyrrhetinic Acid in the stomach and large intestine, and that most of the Glycyrrhetinic Acid formed was absorbed from the large intestine.

Cantelli-Forti et al. (1994) and Wang et al. (1995) reported that more Glycyrrhizic Acid is absorbed in the intestine after oral administration of pure Glycyrrhizic Acid than after an oral administration of licorice extract with equal Glycyrrhizic Acid content. The authors suggested that other constituents of licorice extract inhibit the intestinal absorption of Glycyrrhizic Acid.

Human

Terasawa et al. (1986) measured the disposition of Glycyrrhetinic Acid in healthy human subjects. Five healthy male subjects (aged 20 to 24 years) each ingested 5 g of licorice dissolved in 100 ml water. The dose was determined by HPLC to contain 133 mg Glycyrrhizic Acid and no detectible Glycyrrhetinic Acid. Volunteers were prohibited from consuming alcohol but were not otherwise restricted in normal diet and activities. Blood was collected daily for 7 days after administration. Urine was collected every 10 h over the 7-day post-dose period. Glycyrrhetinic Acid and Glycyrrhizic Acid concentrations in the serum were measured using an enzyme immunoantibody assay. Urinary levels were measured by HPLC.

The maximum serum Glycyrrhizic Acid occurred at 4 h and levels rapidly decreased afterwards. By the 96th h, Glycyrrhizic Acid was undetectable in the sera of all subjects. Likewise, urinary Glycyrrhizic Acid peaked at the first 10-h collection after dose administration and then rapidly decreased. Serum Glycyrrhetinic Acid concentrations peaked at 30 ng/ml about 24 h after dosing and then declined. Four subjects had low but detectable serum Glycyrrhetinic Acid at 48 h, and two at 96 h. Glycyrrhetinic Acid appeared in the urine at the 20- and 30-h time points and decreased at a rate consistent with serum levels. Total urinary excretion of Glycyrrhetinic Acid was about 2% of the administered dose (Terasawa et al. 1986).

Yamamura et al. (1992) investigated the pharmacokinetics of Glycyrrhetinic Acid in human subjects. Three healthy volunteers received a single oral dose of 100 mg Glycyrrhizic Acid in tablet form. Demographics (sex, age, etc.) of the subjects were not reported. Blood was drawn from a cannula in the forearm 1 h before and 0.5, 1, 2, 4, 6, 8, 10, and 12 h after dosing. Urine was collected for a 24-h period after dosing. Diet and beverage were controlled during the study duration. Glycyrrhizic Acid was not detected in plasma after oral administration. Glycyrrhetinic Acid was detected at <200 ng/ml. Total urinary excretion of Glycyrrhizic Acid and its metabolites over the 24-h post-dose period for each of the subjects was 0.8%, 0.3%, and 0.4% of the administered dose.

The stability of Glycyrrhizic Acid in gastric juices at 37°C and pH 1.78 was examined. After 5 h, the hydrolysis products glycyrrhetinic acid 3-*O*-glucuronide and Glycyrrhetinic Acid were not detected. Thus, Glycyrrhizic Acid does not appear to be hydrolyzed in the stomach and is absorbed as intact Glycyrrhizic Acid.

Three healthy volunteers received either 40, 80, or 120 mg Glycyrrhizic Acid by intravenous infusion in the right forearm. Demographics (sex, age, etc.) of the subjects were not reported. Blood was drawn from a cannula in the forearm 1 h before administration and 5, 15, and 30 min, and 1, 2, 4, 6, 8, 10, and 12 h after dosing. Urine was collected for a 24-h period after dosing. The plasma concentration of Glycyrrhizic Acid decreased in a biphasic manner. The half-life of intravenously administered Glycyrrhizic Acid at the three dose levels was 3.8 to 4.8 h and total body clearance was 16 to 25 ml/kg/h. The steady-state volume of distribution was 78 to 98 ml/kg. Urinary excretion of Glycyrrhizic Acid over 24 h amounted to 1.1% to 2.5% of the administered dose. The metabolites, glycyrrhetininc acid 3-*O*-glucuronide and Glycyrrhetinic Acid, were not detected in plasma or urine (Yamamura et al. 1992).

Ploeger (2001b) compared the pharmacokinetics of Glycyrrhetinic Acid after a single dose and after multiple doses in humans. Twelve healthy male volunteers, aged 19 to 29 years with a mean body weight of 70 ± 6.6 kg, ingested 130 mg/day Glycyrrhetinic Acid in a propylene glycol and water vehicle for 5 days. Blood samples were collected prior to dosing and at several time points after dosing on the 1st and 5th days and again 5 days after the last dose. Urine was also collected throughout the study. After the first dose, the maximum plasma concentration (C_{max}) of Glycyrrhetinic Acid was achieved within 4 h post-dose, C_{max} was 1.11 ± 0.94 mg/L. After the fifth dose, the C_{max} was 1.80 ± 0.95 mg/L. Time to C_{max} after the fifth dose was not reported. The half-life of Glycyrrhetinic Acid was 23.6 h. Glycyrrhetinic Acid (0.028 ± 0.044 mg/L) was still detectable in the subjects' plasma 219 h after the last dose.

Tanaka et al. (1993) studied the phamacokinetics of Glycyrrhizic Acid in patients with chronic hepatitis. Hepatitis patients, aged 38 to 69, received an intravenous injection of 120 mg Glycyrrhizic Acid. Plasma concentrations of Glycyrrhizic Acid were monitored for 10 h after dosing and declined in a monophasic manner. The mean biological half-life of Glycyrrhizic Acid was 6.0 ± 2.1 h, the mean total clearance was 7.9 ± 3.0 ml/h/kg, and the mean volume of distribution was 61.8 ± 18.3 ml/kg.

GENERAL BIOLOGY

Systemic Effects Overview

Moderate chronic or high acute exposure to Glycyrrhizic Acid, Ammonium Glycyrrhizate, and their metabolites have been demonstrated to cause several transient systemic alterations, including increased potassium excretion, sodium and water retention, body weight gain, alkalosis, suppression of the renin-angiotensis-aldosterone system, hypertension, and muscular paralysis. Most of these effects are the consequence of the Glycyrrhizic Acid inhibition of the enzyme 11β-hydroxysteroid dehydrogenase-2 (11β-OHSD2) in the kidney. This enzyme protects mineralocorticoid (aldosterone) receptors from being stimulated by cortisol. Stimulation of mineralocorticoid receptors in the distal renal tubules causes the excretion of potassium and hydrogen ions in the urine and the reabsorption of sodium bicarbonate and water. Retention of sodium and water causes hypertension. Reabsorption of bicarbonate causes alkalosis. Hypokalemia resulted in myoglobinuria, which caused muscular weakness and paralysis. Ataxia has been observed after a very high acute exposure to Glycyrrhizic Acid. These effects dissipate when exposure to Glycyrrhizic Acid is ceased, and these effects can be blocked by the mineralocorticoid receptor antagonists spironolactone and eplerenone (Olukoga and Donaldson 2000; Davis and Morris 1991; Conn et al. 1968).

Animal

Finney et al. (1958) observed a marked antidiuretic effect in rats within 30 min after a single i.p. dose of 125 mg/kg Glycyrrhetinic Acid. Sodium retention and increased urinary excretion of potassium were also observed.

Rossi et al. (1994) compared the pharmacological effects of Glycyrrhizic Acid and 18β-Glycyrrhetinic Acid in rats. Normotensive Sprague-Dawley rats received 30 mg/kg/day Glycyrrhizic Acid or 15 mg/kg/day 18β-Glycyrrhetinic Acid by oral intubation for 30 days (exact sample size not reported, $n \geq 10$ per dose group). A control group of unspecified size received a comparable volume of water on the same dosing schedule. Systolic blood pressure was measured prior to the first dose and on the 7th, 15th, and 30th day of treatment. In order to reduce stress-induced effects while measurements were made during the study, all animals were acclimated to the blood pressure measuring procedure prior to study initiation. The day prior to the first dose and on days 6, 14, and 29 of dosing, rats were placed in metabolism cages, and 24-h urine samples were collected. The urine volume was recorded and the urine was analyzed for electrolyte content. Additional systolic blood pressure measurements and urine samples were collected on day 60 (30 days after the last dose).

Systolic blood pressure was significantly increased at 15 days in the Glycyrrhizic Acid and the 18β-Glycyrrhetinic Acid groups ($p < 0.05$) and at 30 days in the 18β-Glycyrrhetinic Acid group only ($p < 0.01$). Urine volume was decreased and urine Ca^{2+} concentration was increased in the 18β-Glycyrrhetinic Acid group at 15 and 30 days. All parameters returned to normal by day 60. The authors concluded that 18β-Glycyrrhetinic Acid is an active agent in the hypertensive effects seen in excessive licorice consumption, and that these effects are reversible (Rossi et al. 1994).

Rossi et al. (1999) studied the effects of Glycyrrhizic Acid and the 18α- and 18β- isomers of Glycyrrhetinic Acid on heart function, cardiac tissues, and apoptosis. This study had two parts, acute treatments and subchronic treatments. In the acute treatment, Sprague-Dawley rats were given a single intraperitoneal injection of 0.5, 1.0, or 1.5 mg/kg of Glycyrrhizic Acid, 18α-Glycyrrhetinic Acid, or 18β-Glycyrrhetinic Acid ($n = 4$ rats per dose per test material). An additional group of four rats received 2.0 mg/kg 18α-Glycyrrhetinic Acid, of which all died within 140 min of dosing due to atrioventricular block, as detected by electrocardiogram (ECG). The ECG profiles of all other animals were similar to controls. Microscopic examination showed no abnormalities in the surviving rats. However, edema in the brain, cerebellum, and lungs, and hematic stasis in the kidneys occurred in the 2.0 mg/kg 18α-Glycyrrhetinic Acid group. Calculi of calcium salt occurred in the renal tubules of two of the dead rats. Focal changes in the papillary muscles of the heart included edema, myolysis, and cell distortion. Terminal deoxynucleotidyl transferase biotin-dUTP nick end labeling (TUNEL) analysis of the papillary muscles of the heart indicated evidence of apoptosis in the 18α-Glycyrrhetinic Acid group.

In the subchronic treatment, Sprague-Dawley rats were assigned to four treatment groups and received daily oral doses of 30 mg/kg Glycyrrhizic Acid, 15 mg/kg 18β-Glycyrrhetinic Acid, 15 mg/kg 18α-Glycyrrhetinic Acid, or an equal volume of water (control) for 30 days ($n = 40$ rats per group on day 0 of dosing). Ten rats per group were killed prior to the first dose. Ten rats per group were killed on day 15 of dosing and another 10 on day 30 of dosing. The remaining 10 animals per group were kept alive an additional 30 days following the treatment period, at which time they were killed. Twenty-four hours prior to scheduled deaths, animals were placed in metabolism cages for urine collection. Blood was collected at death, and tissues and organs were examined microscopically. Certain tissues were set aside for apoptosis analysis by the TUNEL assay.

At 15 days urine electrolyte analysis had potassium (K^+) increased in the Glycyrrhizic Acid group and sodium (Na^+), and calcium (Ca^{2+}) increased in the 18α-Glycyrrhetinic Acid group; at 30 days, K^+ and Na^+ in the 18α-Glycyrrhetinic Acid group, and K^+ and Ca^{2+} increased in the 18β-Glycyrrhetinic Acid

group; and at 60 days (30 days after last dose), Na^+ increased in the Glycyrrhizic Acid group, and K^+ and Ca^{2+} increased in the 18α-Glycyrrhetinic Acid group (all urine electrolyte differences reported were significant at $p < 0.05$). Na^+ levels were elevated in serum of all three treatments at 15 and 30 days but returned to normal by day 60. Myolysis of the papillary muscles appeared in the Glycyrrhizic Acid and 18α-Glycyrrhetinic Acid group at day 30 and did not regress over the 30-day recovery period. Animals in these two treatment groups also had tubular caliculi in the bronchus-associated lymphoid tissue at day 15 and thereafter. Renal calculi occurred in concert with increased urinary Ca^{2+} (see above). In this study 18α-Glycyrrhetinic Acid was the most potent cardiotoxin of the three compounds studied, and while some effects occurred and ceased with exposure, other damage (e.g., myolysis) persisted after exposure had ended (Rossi et al. 1999).

Human

Ploeger et al. (2001b) studied the inhibitory effect of Glycyrrhetinic Acid on 11β-hydroxysteroid dehydrogenase-2 (11β-OHSD2) by measuring the cortisol cortisone ratio in urine before and after human exposure to Glycyrrhetinic Acid. Twelve healthy male volunteers, aged 19 to 29 years with a mean body weight of 70 $\pm$ 6.6 kg, refrained from eating any licorice or Glycyrrhetinic Acid-containing foods for 72 h prior to and throughout the study. The subjects did not eat or drink anything except water for 10 h before dose administration. Urine was collected for 24 h before the first dose was given. Subjects ingested 130 mg/day Glycyrrhetinic Acid in a propylene glycol and water vehicle for 5 days. Blood samples were collected prior to dosing and at several time points after dosing on the 1st and 5th days and again 5 days after the last dose. Urine was also collected throughout the study.

The ratio of cortisol/cortisone was significantly increased on days 2, 3, 4, and 5 of dosing, compared to baseline data. Also, the ratio of cortisol/cortisone increased with each successive day of dosing. Because 11β-OHSD2 is the enzyme responsible for converting active cortisol to inactive cortisone ("active" here is in reference to activity as an aldosterone receptor antagonist), the inhibition of 11β-OHSD2 by Glycyrrhetinic Acid (or its metabolite Glycyrrhizic Acid) caused the changes in cortisol/cortisone ratio. The median concentration of inhibition (IC_{50}) of 11β-OHSD2 was between 325 and 394 μg/L Glycyrrhetinic Acid in plasma (Ploeger et al. 2001b).

Molhuysen et al. (1950) stated that licorice extract was found to be an effective treatment for gastric ulcers during World War II, but edema occurred in about 20% of the patients receiving this treatment. To investigate possible causes of edema, these authors administered a licorice extract (succus liquiritiæ) containing 15% Glycyrrhizic Acid to seven patients who had persistent gastric ulcers and to three patients who did not. Subjects received 20 to 45 g of the licorice extract, administered in eight equal parts (2-h intervals) throughout the day and night (duration of treatment was not specified, but seemed to vary with each patient). Urine was collected at each dose interval. Subjects were on a strictly controlled diet during the experiment.

Urine output volume decreased within the first 3 days of treatment, as did chloride (Cl^-) excretion. Excretion of urea plus ammonia was not affected, nor was urea clearance. There was no albumin or abnormal urinary sediment detected in the urine. Blood hemoglobin level decreased with dosing. Venous blood pressure, pulse pressure, and systolic pressure all increased significantly. Patients also gained several kilograms in body weight due to edema. The authors attributed this combination of effects to "stimulation of the renal tubules to an excessive reabsorption of water and chlorides, and probably also of sodium." Another patient received an unspecified amount of pharmaceutical Ammonium Glycyrrhizate, and the effects were similar to those receiving the licorice extract (Molhuysen et al. 1950).

Louis and Conn (1956) administered seven normal human subjects 6 g/day Ammonium Glycyrrhizate for three days. Compared to baseline data before dosing, sodium (Na^+) and chloride (Cl^-) excretion in the urine was significantly decreased while potassium (K^+) excretion was slightly increased during the dosing period. Withdrawal of the Ammonium Glycyrrhizate caused an immediate above-normal increase in renal excretion of Na^+ and Cl^- and retention of K^+. During the exposure period, four subjects gained weight attributed to water retention. Body weights returned to normal 5 to 7 days after withdrawal of Ammonium Glycyrrhizate treatment. Details of other effects are described in Clinical Experimental Studies.

Hormonal Effects

Quaschning et al. (2001) demonstrated that inhibiting the aldosterone (mineralocorticoid) receptor prevents the hypertension normally induced by Glycyrrhizic Acid in rats. Glycyrrhizic Acid (3 g/L) was added to the drinking water of Wistar-Kyoto rats for 21 days. From days 8 to 21, 5.8 mg/kg/day spironolactone, 182 mg/kg/day eplerenone, or a placebo was added to the diet ($n = 7$ animals/group). Glycyrrhizic Acid increased systolic blood pressure from 142 to 185 mm Hg. Spironolactone and eplerenone, known antagonists of the aldosterone receptor, normalized blood pressure in animals also given Glycyrrhizic Acid.

Takii et al. (2001) demonstrated an anti-diabetic effect of Glycyrrhizic Acid in genetically diabetic mice. Male 4-week-old KK-A^y/Ta Jcl mice with genetic type II non–insulin-dependent diabetes were given control diet, diet containing 0.27% Glycyrrhizic Acid, or diet containing 0.41% Glycyrrhizic Acid for 9 weeks ($n = 8$ mice/group, matched for body weight and blood glucose concentration). Animals were fasted for 5 h, and blood was collected for analysis before, weekly during, and after the treatment period. Animals were killed for necropsy after the treatment period.

Food consumption and body weight gain did not differ between treatment groups. Water consumption was decreased at week 7 and thereafter. Five-hour fasting blood glucose

levels were similar between groups until week 7 of treatment, when the control group had increased blood glucose levels, whereas Glycyrrhizic Acid–treated mice maintained steady blood glucose levels. At week 8, the blood glucose of the 0.27% Glycyrrhizic Acid group increased to match that of the control group. At weeks 8 and 9, the blood glucose of the 0.41% Glycyrrhizic Acid group was significantly less than that of the other two groups. At week 9, the blood insulin level of the 0.41% Glycyrrhizic Acid group was significantly less ($p < 0.05$) than that of the other two groups.

After week 9, an oral glucose tolerance test was performed in which the mice received an oral dose of 200 μl 20% glucose solution (1 g/kg glucose) after an 18-h fast. Blood samples were taken before the glucose dose and 30, 60, and 120 min after. Blood glucose levels of the 0.41% Glycyrrhizic Acid group at 60 and 120 min were significantly less ($p < 0.05$) than the blood glucose levels of the control group and 0.27% Glycyrrhizic Acid group, which were similar. Necropsy did not reveal any remarkable effects of Glycyrrhizic Acid treatment. The authors proposed that Glycyrrhizic Acid inhibits the Na^+-glucose active transport system in the small intestine, but further studies would be required to investigate the mechanism (Takii et al. 2001).

Cardiac Effects

Glycyrrhizic Acid and related compounds can increase blood pressure by promoting the retention of sodium and water from the kidneys and suppression of the aldosterone-renin-angiotensin system as described above.

Kilgore et al. (1998) discovered that treatment with Glycyrrhizic Acid but not Glycyrrhetinic Acid can reduce the size of myocardial infarcts in rabbits. New Zealand white rabbits were anesthetized, and the left jugular vein was cannulated for drug administration and blood sampling. The left carotid artery was cannulated and connected to a transducer to monitor systolic blood pressure. Thoracotomy and pericardiotomy were performed on each rabbit. A silk suture was placed around the left coronary artery to occlude blood flow for 30 min. Ischemia was confirmed by cyanosis distal to the site of occlusion. At the end of the occlusion period, the suture was released to allow reperfusion of the cardiac tissue. Animals received an i.v. bolus infusion of 10 mg/kg/h Glycyrrhizic Acid or 10 mg/kg/h Glycyrrhetinic Acid immediately before reperfusion and every hour for 5 h ($n = 6$ rabbits/group). Eleven control animals received saline infusions on the same schedule. Blood was collected at hourly intervals. After the 5-h reperfusion and dosing period the infarcted area was determined by perfusion of the heart with dyes that are metabolized by healthy tissue. The dyes differentiated between tissue unaffected by the occlusion of the left coronary artery (red), noninfarcted tissues that became ischemic during the occlusion (purple-black), and infarcted tissue (pale yellow).

There was no difference between treatment groups in the area affected by the occlusion. However, 59.3% of the occlusion-affected area was infarcted in the control group, whereas that percentage was only 30.3% in the Glycyrrhizic Acid group, a statistically significant difference ($p < 0.05$). When expressed as percent of the left ventricle, 27.5% was infarcted in control rabbits while 13.0% was infarcted in the Glycyrrhizic Acid group, also a significant difference ($p < 0.05$). The infarcted area of the Glycyrrhetinic Acid group was similar to that of control animals. The myeloperoxidase activity in left ventricle tissue of the Glycyrrhizic Acid group was lower than that of control animals. The authors suggest that Glycyrrhizic Acid is effective in reducing the degree of myocardial injury after an acute period of ischemia and reperfusion (Kilgore et al. 1998).

Effects on Enzyme Activities

Whitehouse et al. (1967) found that Glycyrrhetinic Acid at 100 mM is a potent inhibitor of oxidative phosphorylation coupled to succinate oxidation in rat liver mitochondria.

O'Brian et al. (1990) demonstrated that Glycyrrhetinic Acid inhibits the calcium- and phospholipid-dependent phosphotransferase activity of protein kinase C (PKC). The IC_{50} of PKC inhibition was approximately 450 μM Glycyrrhetinic Acid. Glycyrrhizic Acid was a much weaker inhibitor of PKC activity.

Jung et al. (2001) exposed B16/F10 murine melanoma cells to Glycyrrhizic Acid or Glycyrrhetinic Acid for three days and then determined the melanin contents and tyrosinase activities in the cells. Cellular melanin content and tyrosinase activity were dose dependently increased by Glycyrrhizic Acid. However, the rise in melanin content reached a plateau of 160% of control at 0.50 mM Glycyrrhizic Acid, whereas tyrosinase activity continued to rise 220% of control at the highest concentration tested, 1.00 mM Glycyrrhizic Acid. Additionally, the intracellular levels of tyrosinase mRNA and expression of tyrosine-related protein-2 (TRP-2), but not TRP-1, were also dose dependently increased by Glycyrrhizic Acid. These effects were not seen when the cells were treated with Glycyrrhetinic Acid. Rather, Glycyrrhetinic Acid caused decreases in tyrosinase activity and melanin content. These data indicate that the glycoside structure is important in the Glycyrrhizic Acid–induced stimulation of melanogenesis in this cell line.

Noda (1964) found that 0.13 to 4 mmol/L Glycyrrhizic Acid inhibited the enzyme activity of proteinase in an in vitro system. This inhibition was greater at higher Glycyrrhizic Acid concentrations.

Paolini et al. (1998) studied the effects Glycyrrhizate on the cytochrome P450 monooxygenase activities in Swiss Albino CD1 mice. The mice received daily oral doses of 480 mg/kg Glycyrrhizic Acid for 1, 4, or 10 days. Controls received vehicle only. Animals were fasted for 16 h after the last dose and then killed. The livers were rapidly removed and prepared for enzymatic assays, electrophoresis, Western immunoblot, RNA isolation, and Northern hybridization. The single dose of Glycyrrhizic Acid did not induce any enzymes. However, hepatic cytochrome P450 (CYP) 3A-, 2B1-, and 1A2-dependent

microsomal monooxygenase were induced by the multiple doses of Glycyrrhizic Acid. The following testosterone hydroxylase (TH) enzymes in the liver were also induced by multiple doses of the two test materials: 6β-TH, 2α-TH, 6α-TH, 7α-TH, and 16β-TH. The authors suggested that these results indicate that the induction of cytochrome P450-dependent activities by the prolonged intake of Glycyrrhizic Acid at high doses may cause accelerated metabolism of coadministered drugs, and that the adverse effects associated with cytochrome P450 changes may also have clinical consequences.

Sakamoto et al. (2001) found that Glycyrrhizic Acid binds to high mobility group proteins 1 and 2 (HMGP1/2), causing a conformational change in the proteins, and thus inhibiting the phosphorylation of HMPG1/2 by protein kinases. Glycyrrhetinic Acid had 10 times the binding affinity of Glycyrrhizic Acid to HMPG1/2. HMPG1/2 requires phosphorylation for its DNA-binding affinity; however, the physiological significance of this DNA-binding was unclear. Blockade of HMPG1/2 by Glycyrrhizic Acid or Glycyrrhetinic Acid may be involved in the anti-inflammatory activity of these compounds.

Gap Junction Inhibition

As described by Rozental et al. (2001), gap junctions are pores connecting the cytoplasm of adjacent cells and are important for intercellular communication and normal function in several tissue types. Glycyrrhetinic Acid and its derivatives reversibly block gap junction communication. 18α-Glycyrrhetinic Acid and 18β-Glycyrrhetinic Acid mediate a concentration-dependent inhibition of junctional conductance by 60%. Complete blockade of the gap junction channels does not occur even at concentrations as high as 100 μM. Concentrations above 75 μM Glycyrrhetinic Acid become cytotoxic and irreversible damage occurred. The mechanism for action is unknown. The inhibitory effect of Glycyrrhetinic Acid and its derivatives is used as a tool in electrophysiology experiments and other areas of cellular research.

Davidson and Baumgarten (1988) studied the structure-activity relationship of Glycyrrhetinic Acid derivatives as gap junction inhibitors in human fibroblasts. The authors reported the relative potencies of the test compounds in terms of median concentration of inhibition of gap junction channels (IC_{50}) and median toxic concentration (TC_{50}). For 18α-Glycyrrhetinic Acid, the IC_{50} was 1.5 μM, and the TC_{50} was $>$100 μM. For 18β-Glycyrrhetinic Acid, the IC_{50} was 2 μM, and the TC_{50} was 25 μM.

Gou et al. (1999) found that 18α-Glycyrrhetinic Acid inhibits communication between alveolar epithelial cells at concentrations as low as 5 μM. Extended exposure of alveolar epithelial cells to higher concentrations of 18α-Glycyrrhetinic Acid caused inhibition of gap junction intracellular communication and time- and concentration-dependent reductions in Cx43 protein and mRNA expression. Cx43 is one of the proteins responsible for gap junction formation.

Schiller et al. (2001) found that gap junction intercellular communication between cultured MC3T3-E1 osteoblastic cells was concentration-dependently inhibited by 100 μM 18α-Glycyrrhetinic Acid. Likewise, the blockade of gap junctions by 18α-Glycyrrhetinic Acid interfered with the maturation of the osteoblastic cells, possibly by affecting signal regulating the expression of genes involved in maturation and/or differentiation.

Bou-Flores and Berger (2001) used 50 μM 18α- and 18β-Glycyrrhetinic Acid in neuronal slice preparations from neonatal Swiss Webster mice to demonstrate the importance of gap junction coupling in interneuronal communication in the central respiratory rhythm-generating system.

Böhmer et al. (2001) measured the effects of 18β-Glycyrrhetinic Acid on electrolyte transmission between confluent primary cultures of rat hepatocytes. 18β-Glycyrrhetinic Acid at 40 μM did not affect Na^+ and K^+ conductance, but it did block the conductance of Cl^-.

Tabernero et al. (2001) found that gap junction communication is important in the metabolic syncytium of sharing energetic intermediates among astrocytes. Inhibition of gap junctions by 100 μM 18α-Glycyrrhetinic Acid caused increased glucose uptake in individual astrocyte cells and induced astrocyte proliferation.

Cytotoxicity

Babich et al. (1993) studied the cytotoxicities of the 18α- and 18β- stereoisomers of Glycyrrhetinic Acid among a list of dietary non-nutrients with chemopreventive properties. Cytotoxicity was measured with the neutral red assay, using BALB/c mouse 3T3 fibroblasts as indicators. The neutral red assay quantifies the number of viable, uninjured cells after incubation with a test compound and is based on the uptake and lysosomal accumulation of neutral red dye. Relative toxicity was reported as the concentration at which the count of dead cells was 50% of control cells (NR_{50}). The range of concentrations used was not reported. The NR_{50} values for 18α-Glycyrrhetinic Acid and 18β-Glycyrrhetinic Acid were 0.26 mM and 0.13 mM, respectively. For comparison, 18α-Glycyrrhetinic Acid and 18β-Glycyrrhetinic Acid were more cytotoxic than caffeic acid (NR_{50} = 1.1 mM), vanillin (8.0 mM), and D-saccharic acid 1,4-lactone (18.6 mM), and less toxic than benzyl isothiocyanate (0.019 mM) and tamoxifen (0.016 mM).

Hepatotoxin Protection

Kiso et al. (1984), noting that Glycyrrhizic Acid and Glycyrrhetinic Acid have been shown to protect liver tissue from known hepatotoxins such as carbon tetrachloride (CCl_4) and galactosamine, exposed rat hepatocytes in primary culture to medium containing 10 mM CCl_4 or 0.5 mM D-galactosamine with 0.01, 0.1, or 1.0 mg/ml Glycyrrhizic Acid or 0.01, 0.1, or 1.0 mg/ml Glycyrrhetinic Acid. The concentration of glutamic-pyruvic transaminase (GPT) in the medium was used as a measure of cytotoxicity. Glycyrrhizic Acid and Glycyrrhetinic Acid

at the 0.1 and 1.0 mg/ml concentrations each showed a dose dependent decrease in the GPT levels, compared to hepatotoxin treatment without Glycyrrhizic Acid or Glycyrrhetinic Acid. The 0.01 mg/ml concentrations of Glycyrrhizic Acid or Glycyrrhetinic Acid did not protect the cells from cytotoxicity. Glycyrrhetinic Acid at 1.0 mM also decreased the generation of free radicals induced by CCl_4 in rat liver microsomes. Glycyrrhetinic Acid at 0.01, 0.1, and 1.0 mg/ml reduced the lipid peroxidation induced by ADP/Fe^{3+} or ascorbate/Fe^{3+} in rat liver microsomes. The authors suggested that Glycyrrhizic Acid or Glycyrrhetinic Acid may be hepatoprotective by preventing lipid peroxidation and free radical generation.

Shibayama (1989) treated male Wistar rats with 200 mg/kg Glycyrrhizic Acid in saline intraperitoneally (i.p.) or by injection into the tail vein. Two or 20 h after the Glycyrrhizic Acid injection, the rats received a hepatotoxin: 0.15 ml/kg CCl_4 in olive oil injected i.p.; 0.1 ml/kg allyl formate in saline injected i.p.; or 3 mg/kg endotoxin in saline injected i.p. or via the tail vein ($n = 3$ rats/treatment condition). Appropriate vehicle controls were used for each combination of Glycyrrhizic Acid and hepatotoxin. The rats were anesthetized 24 h after the hepatotoxin injection, and blood was collected from the inferior vena cava for liver function tests. The livers were fixed and stained for microscopic examinations.

All groups of rats receiving hepatotoxin without Glycyrrhizic Acid had elevated serum glutamic-oxaloacetic transaminase (GOT) and glutamic-pyruvic transaminase (GPT) levels, an indicator of hepatotoxicity. Pretreatment with Glycyrrhizic Acid for 2 h had no effect on the serum GOT and GPT levels given hepatotoxins. Pretreatment with Glycyrrhizic Acid for 24 h significantly reduced ($p < 0.001$) the serum GOT and GPT levels in rats given CCl_4 or allyl formate. Glycyrrhizic Acid did not affect the rise in serum GOT or GPT in rats given endotoxin. There were close relationships between the serum GPT and GOT level and the degree of cellular necrosis seen in the microscopic examinations. Thus, pretreatment with Glycyrrhizic Acid protected the liver from CCl_4 and allyl formate toxicity, but apparently did not affect the hepatotoxicity of endotoxin (lipopolysaccharide B, derived from *Escherichia coli*) (Shibayama 1989).

Nakamura et al. (1985) exposed primary cultures of rat hepatocytes to 0, 1, 2, 3, 4, or 5 mM CCl_4 for 24 h to demonstrate hepatoxocity as measured by the cellular leakage of the cytosolic enzymes lactic dehydrogenase (LDH), GOT, and GPT. CCl_4 at lower doses caused concentration dependent leakage of the enzymes without cytolysis, but cytolysis was seen with 5 mM CCl_4. When the hepatocytes were exposed to 5 mM CCl_4 with 25, 50, 100, or 200 μg/ml Glycyrrhizic Acid, there was a concentration-dependent decrease in the LDH and GOT leakage from the cells, and cytolysis was reduced. These data support the ability of Glycyrrhizic Acid to protect the liver from hepatotoxic injury.

Nose et al. (1994) compared the in vivo and in vitro antihepatotoxic activities of Glycyrrhizic Acid and Glycyrrhetinic Acid. Male Wistar rats received 100 or 300 mg/kg of 18β-Glycyrrhetinic Acid or Glycyrrhizic Acid orally 1, 24, and 48 h (three injections) prior to an i.p. dose of 500 mg/kg D-galactosamine. Additional groups of rats received 18β-Glycyrrhetinic Acid or Glycyrrhizic Acid i.p. 1 h prior to an i.p. dose of 500 mg/kg D-galactosamine. Blood was collected from the hearts of the rats 24 h after the D-galactosamine dose. Serum GOT and GPT activities were determined using transaminase kits. Rats pretreated with 100 or 300 mg/kg 18β-Glycyrrhetinic Acid had significantly decreased ($p < 0.05$) serum GOT and GPT activities than rats given D-galactosamine without the pretreatment. Glycyrrhizic Acid at 100 and 300 mg/kg resulted in a slight but nonsignificant reduction in the enzyme activities.

Rat parenchymal cells in primary culture monolayers were treated with 5, 10 or 50 μg/ml 18β-Glycyrrhetinic Acid or 5, 50, or 1000 μg/ml Glycyrrhizic Acid for 24 h. The cells were then washed and exposed to medium containing 5 mM CCl_4 for 6 h, when transaminase activities in the medium were assayed. All three concentrations of 18β-Glycyrrhetinic Acid reduced the GOT and GPT activities, compared to cultures exposed only to 5 mM CCl_4. Glycyrrhizic Acid only reduced transaminase activities at the 1000 μg/ml concentration.

The authors concluded that these studies demonstrated that 18β-Glycyrrhetinic Acid is a more potent protector against hepatotoxicity than Glycyrrhizic Acid. The authors suggested that the difference in antihepatotoxicity of these two compounds may lie in the transformation rate of Glycyrrhizic Acid to Glycyrrhetinic Acid (Nose et al. 1994).

Lin et al. (1999) used an in vivo study design similar those described above to demonstrate that pretreatment with 200 mg/kg/day Glycyrrhizic Acid or 10 mg/kg/day Glycyrrhetinic Acid i.p. for 3 days protected rats from hepatotoxicity induced by 35 mg/kg i.p. of retrorsine. A single pretreatment with 200 mg/kg/day Glycyrrhizic Acid or 10 mg/kg/day Glycyrrhetinic Acid i.p. did not protect against retrorsine-induced hepatotoxicity.

Hu et al. (2001) demonstrated that 50 μM Glycyrrhizic Acid improved the viability of V79 cells also exposed to 5 mM acetaldehyde or 10 μM cadmium. Glycyrrhizic Acid at up to 200 μM, however, did not prevent cadmium-induced lipid peroxidation in these cells.

Antihepatitis Activity

Crance et al. (1994) demonstrated that Glycyrrhizic Acid at 1000 and 2000 μg/ml concentration dependently inhibited the replication of hepatitis A virus in PLC/PRF/5 cells in vitro in a dose-dependant manner. Glycyrrhizic Acid was not virucidal, but it did inhibit an early stage of replication of the virus. Glycyrrhizic Acid inhibited the penetration of hepatitis A virus through the plasma membranes of the PLC/PRF/5 cells.

In a summary of presentations at a symposium on chronic active liver disease, Fujisawa and Tandon (1994) reported that Glycyrrhizic Acid has been known as a treatment for chronic hepatitis in Japan for over 20 years. The author suggested that Glycyrrhizic Acid appears to inhibit the penetration of hepatitis

virus into hepatocytes and it may also work as a free radical scavenge and modulate the immune system through interferon mechanisms and T cells (Crance et al. 1994).

Iino et al. (2001) randomly selected 100 subjects from a pool of 178 chronic hepatitis patients whose liver function did not improve with 2 weeks of 40 ml/day stronger neo-minophagen C (SNMC), a hepatitis treatment containing 0.2% Glycyrrhizic Acid, 0.1% cysteine, and 20% aminoacetic acid as active ingredients. The 100 patients received 40 ml/day or 100 ml/day SNMC for 3 weeks ($n = 50$/group). Hepatic enzyme function was recorded 4 and 8 weeks prior to the first dose, weekly during the dosing period and weekly for 3 weeks after the last dose. Serum alanine transaminase (ALT) activity was used as a measure to rate improvement in liver function. Six patients in the 100 ml/day SNMC group were unable to complete the experiment, but of those 44 remaining, 23 (52.3%) had improved liver function. Of the 46 patients in the 40 ml/day group that completed the trials, 12 (26.1%) had improvement in liver function. Thus, the 100 ml/day group had significantly more improvement ($p = 0.017$) in liver function than patients in the 40 ml/day group. The authors proposed that patients who do not respond to moderate doses of SNMC might respond better to a higher dose.

van Rossum et al. (2001) gave Glycyrrhizic Acid to patients with chronic hepatitis C who did not respond to interferon therapy. Forty-one patients received 80, 160, or 240 mg Glycyrrhizic Acid by drip infusion three times per week for 4 weeks (number of patients per dose was not reported). Thirteen patients received a placebo three times per week for 4 weeks. In another experiment, 15 patients received 200 mg Glycyrrhizic Acid by intravenous injection six times per week for 4 weeks. Hematological and biochemical assessments were performed weekly during the study. Virological assessments by enzyme-linked immunosorbent assay (ELISA) were done prior to and after treatment. Serum ALT was used to measure hepatic health before and after treatments and was reported in terms of upper limit of normal (ULN), which is 41 IU/L for men and 31 IU/L for women.

Serum ALT levels after placebo treatments were similar to those before the study. In the placebo group, 92% of patients had ALT levels $>1.5\times$ ULN and 8% $<1.5\times$ ULN but higher than normal. Ten percent of the patients that received Glycyrrhizic Acid three times per week had normal ALT levels, whereas 27% and 63% of the patients in that group had ALT levels $<1.5\times$ ULN and $>1.5\times$ ULN, respectively. Of the patients receiving 200 mg Glycyrrhizic Acid six times per week, 20% had normal ALT, 27% had ALT levels $<1.5\times$ ULN, and 53% had ALT levels $>1.5\times$ ULN. Serum ALT levels increased in both Glycyrrhizic Acid groups after treatment ended, and by 4 weeks after the end of treatment, the ALT levels in the dosed groups were similar to the placebo group.

The levels of hepatitis C virus RNA after treatment with Glycyrrhizic Acid were similar to those before treatment. Thus, in chronic hepatitis C patients who do not respond to interferon, hepatic function as measured by serum ALT improves with Glycyrrhizic Acid treament, but the virus appears to be unaffected (van Rossum et al. 2001).

Other Antiviral Activities

Pompei et al. (1979) demonstrated that Glycyrrhizic Acid inhibits the growth of several virus types. Human aneuploid HEp2 cells were prepared into monolayers for 24 h and then infected with vaccinia, herpes simplex 1, Newcastle disease, vesicular stomatitis, or polio type 1 for 1 h. Cells were then washed, and 1, 2, 4, or 8 mM Glycyrrhizic Acid or control medium was applied to the cells for 18 h, when the cells were stained for microscopic examination. Glycyrrhizic Acid at 8 mM completely inhibited the growth of and cell damage caused by vaccinia, herpes simplex 1, Newcastle disease, and vesicular stomatitis. The 2 and 4 mM Glycyrrhizic Acid treatments caused concentration dependent reductions in virus load. Glycyrrhizic Acid at 1 mM did not inhibit any virus growth. The growth of polio type 1 virus was unaffected by any of the Glycyrrhizic Acid concentrations tested.

Badam (1997) tested the anti-viral activities of Glycyrrhizic Acid and Ammonium Glycyrrhizate on the Japanese encephalitis virus (JEV). Porcine stable kidney cells in culture were infected with JEV strains Nakayama, P-20778, or 821564 XY48. One hour after infection, the cells were exposed to various (unspecified) concentrations of Glycyrrhizic Acid, licorice root, or Ammonium Glycyrrhizate for 96 h. Infected control cells received no treatment with licorice-related compounds. The cells were then stained with Amido black, rinsed, dried, and the plaques were counted. The experiments were performed in triplicate. Glycyrrhizic Acid at 500 μg/ml completely inhibited plaque formation in all strains, whereas this effect was seen with Ammonium Glycyrrhizate at 1000 μg/ml. No signs of cytotoxicty were observed at these concentrations.

Additional groups of cells infected with the three strains of JEV were exposed to 500, 1000, or 2000 μg/ml Glycyrrhizic Acid for only 2 h. Cells were stained, and plaques were counted. After 2 h of exposure to Glycyrrhizic Acid, only the 2000 μg/ml treatment caused inhibition of plaque formation, and the inhibition was complete. The two lower concentrations had no effect on plaque formation.

Pretreatment of the cells with 1000 μg/ml Glycyrrhizic Acid for 24 h prior to JEV infection did not affect subsequent plaque formation (Badam 1997).

Utsunomiya et al. (1997) infected 8-week-old BALB/c mice with the mouse-adapted Kumamoto strain of influenza virus A_2 (H_2 N_2) by inhalation with a nebulizer. Viral doses were 1, 10, 20, and 100 times the median lethal dose (LD_{50}) of virus, as determined in preliminary tests. Mice received doses of 1.25 to 80 mg/kg Glycyrrhizic Acid i.p. the day before viral infection and 1 and 4 days after infection. Mice receiving 1, 10, and 20 times the viral LD_{50} and 10 mg/kg or higher doses of Glycyrrhizic Acid had greater survival rate (10 to 20 mice/dose; 100% survival), compared to similarly infected control mice given saline (15 mice; 50% survival). Mean survival time in Glycyrrhizic

Acid–treated mice was greater than that of infected control mice. The grade of pulmonary consolidations and the virus titers in lung tissues were less in treated mice than in infected control mice. Glycyrrhizic Acid had no protective impact on the mice given 100 times the LD_{50} of the virus.

In additional experiments, healthy mice were treated with 0 or 10 mg/kg/day Glycyrrhizic Acid i.p. 1, 3, and 5 days before their spleens were removed. The spleens were processed into single-cell suspensions of intact cells. Whole spleen cells (WSCs) or macrophages, T cells, or B cells derived from WSCs were then injected i.v. into recipient mice at 5×10^6 cells per mouse. Two hours later, the mice were infected with 10 times the LD_{50} of influenza virus. Infected mice that had been given WSCs or T cells from Glycyrrhizic Acid–treated donor mice had a 100% survival rate 21 days after infection. Infected mice given B cells or macrophages from Glycyrrhizic Acid–treated donor mice all died by day 15 after infection. When the donor mice had been given saline and no Glycyrrhizic Acid, the infected recipient mice all died by day 15, regardless of the donor cell type. The authors suggested that Glycyrrhizic Acid protected the mice from the virus through a function of T cells, but not through B cells or macrophages (Utsunomiya et al. 1997).

Sekizawa et al. (2001) applied herpes simplex virus type 1 (HSV1) to the abraded corneas of 66 young female SJL mice to infect the mice with herpetic encephalitis. Fifty mice were given i.p. injections of 50 μg/g/day Glycyrrhizic Acid on post-infection days 3, 4, and 5. Fifty control mice received the vehicle physiological saline without Glycyrrhizic Acid. Mice were monitored until post-infection day 14. The survival rates at post-infection day 14 were 81.8% for the mice given Glycyrrhizic Acid and 37.5% in infected control mice. The brains from 26 Glycyrrhizic Acid–treated mice and 25 control mice were removed on post-infection day 6 and processed for a plaque assay to determine propagation of the HSV1 virus in the mouse brains. The brains of mice treated with Glycyrrhizic Acid had 45.6% of the number of plaque forming units (PFU) found in the control mice. Thus, the survivability of HSV1-infected mice was improved with Glycyrrhizic Acid treatment, which also decreased the propagation of the virus in the brain.

Anti-Inflammatory Effects

Tangri et al. (1965) induced arthritis in albino rats by injection of formalin into the ankle joints. Normal and arthritic rats received 0 or 2 mg/100 g/day Glycyrrhetinic Acid i.p. for 10 days. The degree of inflammation was determined by the anteroposterior diameter of the feet. The inflammation was significantly decreased ($p < 0.01$) in the ankles of rats treated with Glycyrrhetinic Acid. Without Glycyrrhetinic Acid treatment, the serum ALT and aspartate aminotransferase (AST) of arthritic rats was 57.4% and 33.2% higher, respectively, than of normal rats. Glycyrrhetinic Acid reduced the serum ALT and AST in arthritic rats by 37.4% and 25.4%, respectively. Glycyrrhetinic Acid did not affect the serum AST or ALT level in normal rats.

Amagaya et al. (1984) found that Glycyrrhetinic Acid (3 to 30 mg/kg p.o.) inhibits edema caused by an injection of λ-carrageenan in the hind feet of mice. Glycyrrhetinic Acid (30 mg/kg p.o.) also reduced the granuloma formation on dorsally implanted cotton pellets in mice. The 18α-isomer of Glycyrrhetinic Acid was more potent in these effects than the 18β-isomer.

Rui (1997) found that Glycyrrhetinic Acid inhibited ear edema induced by croton oil in mice. No other details of this study were given.

Gujral et al. (1961) induced arthritis in bilaterally adrenalectomized albino rats by injecting a fomaldehyde solution into the ankle joints daily for five days. In one experiment, the rats received 250 μg/100 g of deoxycorticosterone acetate (DOCA) subcutaneously, 250 μg/100 g DOCA plus 0.5 mg/100 g hydrocortisone orally, or 250 μg/100 g DOCA plus 20 mg/100 g Glycyrrhizic Acid orally. Doses were administered daily for 10 days after the adrenalectomy surgery. Inflammation of the ankle joint was measured by a micrometer screw gauge to determine the linear cross section of the ankle joint. The DOCA-plus-Glycyrrhizic Acid group showed an anti-arthritic effect by having a significantly smaller ($p < 0.01$) ankle diameter than the other groups.

In a second experiment using the same arthritis model, rats received 0.5 mg/100 g hydrocortisone orally or 20 mg/100 g Glycyrrhizic Acid plus 0.5 mg/100 g hydrocortisone orally. Doses were administered daily for 10 days after the adrenalectomy surgery. Ankle diameter was measured with a micrometer screw gauge as above. The Glycyrrhizic Acid with hydrocortisone group had significantly smaller diameter ankles ($p < 0.005$) than the group that only received hydrocortisone (Gajral et al. 1961).

Ohuchi et al. (1981) found that in rats Glycyrrhizic Acid inhibits prostaglandin E_2 in activated peritoneal macrophages. Sprague-Dawley rats received 5 ml/kg i.p. injections of 5% bacto peptone and 5% soluble starch in solution in order to stimulate macrophage migration. The rats were killed and peritoneal macrophages were isolated and seeded in culture at 6×10^6 cells/60 mm dish and incubated for 2 h. Non-adherent cells were washed away, and the replacement medium contained 0.1, 1, 10, 100, or 1000 μg/ml Glycyrrhizic Acid or Glycyrrhetinic Acid in ethanol for 20 h. Control plates contained only medium with the ethanol vehicle. Sheep red blood cells were added to the medium, and 95% of them had been ingested within 2 h. Prostaglandin E_2 in the medium was determined by radioimmunoassay. Glycyrrhizic Acid and Glycyrrhetinic Acid each concentration dependently inhibited prostaglandin synthesis at 100 and 1000 μg/ml. However, the Glycyrrhetinic Acid caused detachment of 30% of the cells after just 8 h of exposure, which was seen as a cytotoxic effect. In an additional experiment, 3000 μg/ml Glycyrrhizic Acid also inhibited the release of arachidonic acid from macrophages. The authors proposed that the known anti-inflammatory effect of Glycyrrhizic Acid may be partially due to inhibition of prostaglandin E_2.

OTHER CELLULAR EFFECTS

Horigome et al. (2001) found that Glycyrrhetinic Acid caused apoptosis in splenocytes and thymocytes in C57BL/6 mice that had received an i.p. injection of 2.5 mg/animal. Additional in vitro studies indicated that the apoptosis of splenocytes was a result of the inhibition of 11β-hydroxysteroid dehydrogenase by Glycyrrhetinic Acid, which increased the levels of corticosterone.

Glycyrrhizic Acid has also been reported to enhance the production of interleukin-12, interleukin-2, and interferon (Dai et al. 2001; Utsunomiya et al. 2001; Abe et al. 1982; Zhang et al. 1993).

Interactions with Other Chemicals

Hydrocortisone

Teelucksingh et al. (1990) conducted several experiments to study the ability of Glycyrrhetinic Acid to potentiate the activity of hydrocortisone in the skin. Healthy female and male volunteers, aged 21 to 50 years, were treated with test materials on a 7 $\times$ 7-mm site on the flexor side of the forearm. The treatments included 0.1, 0.3, 1.0, 3.0, and 10 mg/ml hydrocortisone acetate, 20 mg/ml Glycyrrhetinic Acid only, and 20 mg/ml Glycyrrhetinic Acid with each of the hydrocortisone concentrations listed above (four to six subjects per treatment). A positive-control group received 0.1, 0.3, 1.0, 3.0, or 10 mg/ml beclomethasone diproprionate. Solutions were prepared in 95% ethanol and made within 24 h before application. After the applied solution had dried, the test area was covered with polyester film for 16 to 18 h. The dose sites were scored for degree of blanching 1, 2, 3, and 6 h after removal of the occlusive dressing. Scoring was performed by observers unaware of the doses applied, and the scale was 0 = none, 1 = mild, 2 = definite, and 3 = intense blanching.

The degree of blanching was presumed to be associated with cutaneous vasoconstriction. Hydrocortisone acetate alone and Glycyrrhetinic Acid alone each had no effect on degree of blanching (vasoconstriction). However, hydrocortisone and Glycyrrhetinic Acid combined produced significant dose-dependent increases ($p < 0.01$–0.001) in the degree of blanching of the skin at the application site, compared to the vehicle control 95% ethanol. Beclomethasone diproprionate, the positive control, produced the expected dose-dependent increase in degree of blanching. The authors concluded that Glycyrrhetinic Acid appeared to potentiate the activity of hydrocortisone in the skin.

Dorsal skin from freshly killed nude mice was removed, homogenized, and proteins were separated and measured. The proteins on suspension were diluted to match the protein content per weight in the skin. The protein suspension was incubated in Krebs-Ringer with 12 nmol/L tritiated corticosterone (82 Ci/mmol) added. This preparation was treated with 0, 0.01, 1.0, or 100 μmol/L Glycyrrhetinic Acid (duration of treatment was not reported). After centrifugation, corticosteroids were extracted from the supernatant, and ^{3}H-11-dehydrocorticosterone was separated by thin-layer chromatography. The percent of corticosterone converted into ^{3}H-11-dehydrocorticosterone was determined.

Glycyrrhetinic Acid significantly inhibited the production of ^{3}H-11-dehydrocorticosterone in a concentration dependent manner ($p < 0.0001$–0.05), thus verifying the inhibition of 11β-OHSD in the skin by Glycyrrhetinic Acid.

Samples of normal, psoriatic, and eczematous human skin were collected from patients. In immunolabeling assays, 11β-OHSD was found in the epidermis with the exception of the basal layer. Distribution of 11β-OHSD was similar in all three skin types, but the activity of the enzyme seemed higher in the psoriatic and eczamatous skin samples.

Given the results of these studies, the authors suggested that by inhibiting the metabolism of hydrocortisone by 11β-OHSD in the dermis, Glycyrrhetinic Acid allowed greater access of hydrocortisone to glucocorticoid receptors (Teelucksingh et al. 1990).

In a commentary in response to the Teelucksingh et al. (1990) study described above, Greaves (1990) suggested that the potentiation of hydrocortisone by Glycyrrhetinic Acid could be due to the ability of Glycyrrhetinic Acid to increase the percutaneous absorption of hydrocortisone.

Diclofenac Sodium

Nokhodchi (2002) applied formulations of 1% diclofenac sodium (nonsteroidal anti-inflammatory) with or without 0.1% to 0.5% Glycyrrhizic Acid to excised abdominal rat skin in Franz-type diffusion cells. Flux of diclofenac sodium into the receptor compartment was measured. The formulation containing 0.1% Glycyrrhizic Acid produced a 10-fold increase in the flux of diclofenac sodium across the rat skin. The formulation containing 0.5% Glycyrrhizic Acid increased the flux of diclofenac sodium by twofold. The author concluded that Glycyrrhizic Acid enhanced the absorption of diclofenac sodium across rat skin.

ANIMAL TOXICOLOGY

Acute Toxicity

Glycyrrhetinic Acid

The median acute lethal dose (LD_{50}) of intraperitoneal (i.p.) injection of Glycyrrhetinic Acid in mice is 308 mg/kg (Informatics, Inc. 1972).

Finney et al. (1958) found that no albino mice died after acute oral or subcutaneous doses of up to 610 mg/kg Glycyrrhetinic Acid. The LD_{50} of Glycyrrhetinic Acid via intraperitoneal route was 308 mg/kg. Of the animals that died, most did so on the second day after dose administration.

Cognis (2002) reported an oral LD_{50} of 610 mg/kg for Glycyrrhetinic Acid in rats.

Ammonium Glycyrrhizate

The LD_{50} of crude Ammonium Glycyrrhizate in mice via oral (p.o.) and i.p. routes are 12,700 and 1050 mg/kg, respectively.

The i.p. LD_{50} of Monoammonium Glycyrrhizate in mice is 1070 mg/kg. Diammonium Glycyrrhizate has p.o. and i.p. LD_{50} values in mice of 9600 and 1250 mg/kg, respectively (Informatics, Inc. 1972).

Food and Drug Research Laboratories (FDRL) conducted acute oral toxicity studies of Ammonium Glycyrrhizate in several species. The LD_{50} values in rats, mice, hamsters, and rabbits were 7.1, 8.6, 8.8 and 10.0 g/kg, respectively (FDRL 1971a).

Inverni della Beffa (1970) studied the acute oral toxicity of Ammonium Glycyrrhizate (also known as Glycamil) in the mouse, rat, and guinea pig. The range of doses used was not reported, but the LD_{50} values for rats and mice were each >5000 mg/kg. The LD_{50} for guinea pigs was >3000 mg/kg.

Fujimura (no date) reported an LD_{50} of 1050 mg/kg for crude Ammonium Glycyrrhizate i.p. in mice. The oral LD_{50} was 12,700 mg/kg. The LD_{50} of refined Ammonium Glycyrrhizate was 1070 mg/kg i.p. The oral LD_{50} of refined Ammonium Glycyrrhizate was >10,000 mg/kg.

Potassium Glycyrrhizinate

The LD_{50} values of Potassium Glycyrrhizinate via p.o., subcutaneous (s.c.), intravenous (i.v.), and intramuscular (i.m.) routes in mice are 1220, 697, 412, and 695 mg/kg, respectively (Informatics, Inc. 1972).

Fujimura (no date) reported an LD_{50} of 1260 mg/kg for crude Potassium Glycyrrhizinate i.p. in mice. The oral LD_{50} was 12,400 mg/kg.

Short-Term Toxicity

Finney et al. (1958) administered intramuscular injections of 10 or 20 mg/kg Glycyrrhetinic Acid to young rats three times a week for four weeks. Rats were killed for examination at the end of the dosing period. There were no clinical effects observed while the animals were alive. At necropsy all tissues were normal except for a slight thinning of the lipid in the zona glomerulosa of the adrenal glands.

Inverni della Beffa (1970) treated eight Wistar rats with 700 mg/kg/day Ammonium Glycyrrizate via oral gavage for 8 weeks. The author described this dose as 150 times greater than the dose used in man as a sweetening agent with respect to body weight. Eight non-treated rats served as a control group.

All animals survived to the end of the treatment period, and there were no indications of intoxication. Weight gain of treated animals was similar to controls. At the end of treatment, examinations of glycemia, hepatic function, diuresis, and urinary excretion of Na^+, K^+, and Cl^- in treated rats were similar to those of control rats. Systolic blood pressure measured in the tail was similar between treated and untreated rats at weeks 4 and 8 of treatment. Hematology and blood chemistry parameters were similar between the control rats and those treated with 700 mg/kg/day.

There were no appreciable differences between treated and control rats in the histological examination of the heart, liver, kidneys, adrenal glands, spleen, and gonads. Of these organs only the liver had a reduced organ weight in treated rats. In this study, reduced liver weight was the only clinical effect noted after 8 weeks of oral treatment with 700 mg/kg/day Ammonium Glycyrrizate (Inverni della Beffa 1970).

In an unpublished report described by Informatics, Inc. (1972), Fujimura and Okamoto fed Dipotassium Glycyrrhizate or Diammonium Glycyrrhizinate to Wistar rats for 90 days. Doses were 0%, 0.1%, and 0.5% test material mixed in feed ($n = 5$ rats/sex/dose). After the 90-day exposure period, the rats were killed and examined. Male rats in the 0.5% groups for each test material had smaller increases in body weight than control rats; females were not affected. No other findings were reported.

Subchronic Toxicity

Inverni della Beffa (1970) tested male mice with 0, 18, or 90 mg/kg/day Ammonium Glycyrrhizate by oral gavage six days a week for 16 weeks ($n = 10$ mice per group). All mice survived the dosing period, and there were no clinical signs of toxicity. The body weight gain of treated mice was similar to control mice. There were no remarkable observations during necropsy examinations.

Rats were exposed using the same protocol. All rats survived the dosing period, and there were no clinical signs of toxicity.

Male rats of the 90 mg/kg/day group had reduced body weights at weeks 9, 10, and 11, but after this period, body weights for all groups were not statistically significant. Female body weights were similar for all groups. Hepatic function, as determined by the measurable degradation of a 50 mg/kg i.v. injection of bromsulphalein, was similar between all groups. There were no treatment-related effects on glycemia or blood pressure. By urinalysis males of the 90 mg/kg/day Ammonium Glycyrrhizate group had increased Na^+ and Cl^- excretion and diuresis at week 8 but not at week 16. Males of the lower dose had diuresis only at week 8 but not at week 16. Female rats had a decrease in Cl^- excretion in the urine at week 16 only. No groups had a difference in renal excretion of K^+.

Analysis of the blood showed a decrease in lymphocytes and increases in neutrophilic granulocytes in males of the higher dose group at week 8, and at week 16 there was a decrease in the total white blood cell count. Female rats of the higher dose had decreased hemoglobin and eosinophilic granulocytes at week 16. Females of the lower dose group had increased hemoglobin and lymphocytes and decreased neutrophylis at week 8 and decreased eosinophilis at week 16.

At necropsy, histological and gross examinations and weights of the major organs did not differ between treatment and control groups (Inverni della Beffa 1970).

Chronic Toxicity

Monlux (1974) fed Ammonium Glycyrrhizate to Osborn-Mendel rats for 2 years. All rats were F_1 offspring of rats in a subacute Ammonium Glycyrrhizate feeding study in which

the F_0 generation were exposed to concentrations of Ammonium Glycyrrhizate (0%, 0.5%, 1.0%, 2.0%, and 4.0%) mixed in powdered rat diet during breeding. No results were available for the F_0 generation. The F_1 rats were fed the same dose as their respective parents' group or control diet for 102 weeks ($n = 10$ rats/group). At the end of the treatment period, all rats were killed and necropsied. Tissues were fixed in formalin and examined microscopically for lesions. The feeding of Ammonium Glycyrrhizate over a period of 2 years did not produce any lesions or anatomic alterations in this study.

Dermal Irritation and Sensitization

Finney et al. (1958) applied cotton-wool pellets saturated with 0.5 ml of a suspension of 100 mg/ml Glycyrrhetinic Acid to the shaved back of albino rabbits. Three pellets were fixed with an adhesive plaster and the trunk of the rabbit was wrapped in a plastic film for 24 h. Another rabbit was similarly treated, except the three exposure sites were abraded before the pellets were applied. There was no evidence of edema or erythema on the intact or abraded exposure sites upon removal of the pellets or 2 days later. Glycyrrhetinic Acid had no apparent primary irritant activity on the skin of the albino rabbit.

Ocular Irritation

Cognis (2002) reported that 6% Glycyrrhetinic Acid in water was classified as "slightly irritating" in an in vitro test using the chorioallantoic membrane of a chicken embryo in hen's egg (HET-CAM) assay. In the assay, 0.3 ml of the test material was applied to the test system (details of the assay were not provided). The irritation potential was evaluated as a function of reaction time and reaction intensity of effects such as hemorrhage, lysis of vessels, and protein coagulation. No reaction to the test material was observed.

GENOTOXICITY

Wang et al. (1991) showed that 0.025, 0.1, and 0.5 μg/plate18β-Glycyrrhetinic Acid concentration-dependently inhibited the mutagenic activities of 10 μg/plate benzo[a]-pyrene, 20 μg/plate 2-aminoflourene, and 0.5 μg/plate aflatoxin B_1 in *Salmonella typhimurium* strains T98 and T100. 18α-Glycyrrhetinic Acid also inhibited the mutagenicity of these compounds but was less potent, as the only effective concentration was 0.5 μg/plate.

Litton Bionetics, Inc. (1972) investigated the mutagenicity of Ammonium Glycyrrhizate, using the host-mediated assay, in vivo and in vitro cytogenetics studies, and the dominant lethal assay. In the host-mediated assay, ICR male rats received Ammonium Glycyrrhizate (dose not specified), which was considered a possible mutagen at the dose levels used in the host-mediated assay. Oral doses of up to 5000 mg/kg Ammonium Glycyrrhizate produced no detectable significant aberration of the bone marrow metaphase chromosomes of rats. Ammonium Glycyrrhizate did not produce significant aberration in the anaphase chromosomes of human tissue culture cells when tested at concentrations up to 1000 μg/ml. Ammonium Glycyrrhizate was considered to be non-mutagenic in rats in the dominant lethal assay at oral doses of up to 5000 mg/kg.

Green (1977) reported that Ammonium Glycyrrhizate was not mutagenic in screening assays in human WI-38 embryonic lung cells, *Saccharomyces cerevisiae* strain D-3, and in the *Salmonella typhimurium* strains G46 and TA1530.

Stanford Research Institute (SRI) evaluated the mutagenic potential of Ammonium Glycyrrhizate with the dominant lethal assay in rats (SRI 1977). Male Sprague-Dawley rats were given 0, 4000, 13,333, or 40,000 ppm Ammonium Glycyrrhizate mixed in the diet for 10 weeks ($n = 20$ male rats/group). After the dosing period, each male was then caged with two virgin females for 7 days for a first mating period, and then the 2nd week with a different pair of virgin females for the second mating. Fourteen days after the midweek of mating, each female was killed and the uteri were removed for fetal examinations.

The male rats of the 40,000 ppm group had significantly reduced ($p < .01$) body weight gain over the 10-week dosing period. The two lower doses of Ammonium Glycyrrhizate did not cause consistent mutagenic effects in the fetuses. Offspring of the 40,000 ppm group had significantly higher ($p < 0.05$) number of dead implants and dead implants/total implants. The authors stated that Ammonium Glycyrrhizate may be a mutagen in the rat at 40,000 ppm (2000 mg/kg/day) in the diet (SRI 1977).

Generoso et al. (1983) evaluated the mutagenic potential of Ammonium Glycyrrhizate in male germ cells, using a dominant lethal assay and a heritable translocation test. In the heritable translocation test, 100 male (101 $\times$ CH3)F_1 mice were each caged with three female (SEC $\times$ C57BL)F_1 mice for 1 week prior to exposure to Ammonium Glycyrrhizate. Then the male mice were separated from the females and fed powdered feed containing 0 or 2.25% Ammonium Glycyrrhizate for 8 weeks ($n = 50$ treated and 50 control). After the exposure period, the males were caged with the same females for 1 week. Male offspring from the two mating periods (before and after exposure) were mated to hybrid stock (SEC $\times$ C57BL)F_1 females. The outcome of these pregnancies were used to measure any inherited effects of Ammonium Glycyrrhizate on male fertility.

Based on data from 475 experimental and 507 control male progeny tested, the authors determined that exposure to Ammonium Glycyrrhizate in this study did not produce any heritable effects on male fertility.

In the dominant lethal assay, male mice were fed powdered feed containing 0% or 2.25% Ammonium Glycyrrhizate for 8 weeks ($n = 36$ treated and 36 control). Beginning immediately after the treatment period each male was caged with one (C3H $\times$ C57BL)F_1 and one (SEC $\times$ C57BL)F_1 virgin females. Females were examined daily for the presence of vaginal plugs for 1 week. Mated females were replaced with new virgins. All matings occurred $1/2$ to $7 1/2$ days after the end of treatment. Pregnant mice were killed 12 to 15 days after appearance of the vaginal plugs. The uteri were examined to determine frequency of pre- and

post-implantation loss. In this study, Ammonium Glycyrrhizate did not induce any dominant lethal effects (Generoso et al. 1983).

Sheu et al. (1986) performed dominant lethal assays of Ammonium Glycyrrhizate in rats and mice and a heritable translocation test in mice. Male rats were fed diet containing 0.4%, 1.3%, or 4.0% Ammonium Glycyrrhizate or corn oil for 10 weeks (n = 20 rats/group). The males were mated with virgin females in the 1st and 2nd weeks after treatment ended. Male fertility was not affected by treatment. However, analysis of the fetuses at day 14 of gestation resulted in a statistically significant ($p < 0.05$) increase in dead implants in females mated to males treated with 4.0% Ammonium Glycyrrhizate. The authors stated that the biological significance of this result is unknown.

Male mice were fed diet containing 2.0% or 2.5% Ammonium Glycyrrhizate or corn oil for 8 weeks (n = 36 mice per group). Immediately after the treatment period, males were mated with virgin females. Females were killed for uterine analysis on gestation days 12 to 15. There was no evidence of infertility or dominant lethal effect in mice.

In the heritable translocation test, groups of 50 to 75 untreated male mice were each caged with three females for 1 week. The females were then caged individually through gestation, whereas the males were fed diet containing 2.25% Ammonium Glycyrrhizate or 2% corn oil (n = 50/group). At the end of the treatment period, the males were paired with the same females for another week of mating. There was no reduction in litter size after treatment with Ammonium Glycyrrhizate. There was no evidence of heritable genetic toxicity in this test (Sheu et al. 1986).

Sasaki et al. (1980) evaluated the in vitro mutagenic potential of Trisodium Glycyrrhizate in Chinese hamster Don-6 cells and in human HE-2144 fibroblastic cells. Treatment of the cells with 0.49 to 2.46 mg/ml Trisodium Glycyrrhizate in the nutrient medium was nonmutagenic.

CARCINOGENICITY

Kobuke et al. (1985) studied the tumorigenicity of Disodium Glycyrrhizate in B6C3F$_1$ mice. Male mice received drinking water containing 0.04%, 0.08%, or 0.15% Disodium Glycyrrhizate (n = 50 to 70 mice per group). The respective Disodium Glycyrrhizate exposure levels in the three dose groups were 2.5, 5.8, and 8.0 mg/kg/day. Female mice received drinking water containing 0.08%, 0.15%, or 0.3% Disodium Glycyrrhizate (n = 50 mice per group). Female exposure levels were 3.5, 6.5, and 12.2 mg/kg/day, respectively. Control groups of 60 male and 50 female mice received distilled drinking water only. The exposure period was 96 weeks, and treated drinking water was replenished every 3 days. After the 96-week treatment period, surviving mice received distilled drinking water without Disodium Glycyrrhizate. Animals that died during the study and those that were killed at the end of the study were examined. Any tumors found were weighed and described. There was no difference between treated and control groups in the tumor incidence, in the latency period before tumor appearance, or in the types of tumors found. The authors suggested that this study provided no evidence that chronic exposure to Disodium Glycyrrhizate was tumorigenic.

ANTICANCER AND TUMOR SUPPRESSION

Wang et al. (1991) reported tht Glycyrrhetinic Acid also inhibited the tumor initiation and tumor promotion by 7,12-dimethylbenz[a]anthracene (DMBA) and 12-O-tetradecanoylphorbol-13-acetate (TPA) in mice. Shaved female SENCAR mice were treated with 10 μmol 18α- or 18β-Glycyrrhetinic Acid in dimethyl sulfoxide (DMSO) or 0.2 ml DMSO vehicle daily for seven days. One hour after the last treatment, 40 nmol DMBA was applied to the same site on all mice. Seven days later, 4 nmol TPA was applied to the same site, and this treatment was continued daily for 16 weeks. In two additional groups, mice were treated with DMSO, DMBA, and TPA as described above, but they were given 10 μmol 18α- or 18β-Glycyrrhetinic Acid topically 30 min before each TPA treatment. Each combination of treatments was performed on 20 mice. Tumors larger than 1 mm that persisted for 2 weeks were counted.

Mice treated with 18α- or 18β-Glycyrrhetinic Acid prior to the tumor initiator DMBA had 20% or 50% fewer tumors, respectively, than control mice. Likewise, mice given 18α- or 18β-Glycyrrhetinic Acid prior to the tumor promotor TPA had 80% and 60% fewer tumors, respectively, than control mice. The authors concluded that topical application of either stereoisomer of Glycyrrhetinic Acid inhibited the binding of radiolabeled DMBA and benzo[a]pyrene (B[a]P) to epidermal DNA. 18α- or 18β-Glycyrrhetinic Acid also inhibited the TPA-induced increases in ornithine decarboxylase activity and lipoxygenase activity in vitro (Wang et al. 1991).

Other studies by Nishino et al. (1984, 1986) and Takasaki et al. (1995) demonstrated that Glycyrrhetinic Acid inhibits the tumor-promoting activity of TPA and teleocidin.

Kitagawa et al. (1986) found that Glycyrrhetinic Acid dose-dependently inhibited the binding of TPA to the TPA receptor in mouse skin. Kinetic analysis suggested that Glycyrrhetinic Acid competitively binds directly to the TPA receptor with an inhibition constant (K_i) of 2.2×10^{-4} M. The concentration required to inhibit 50% of TPA binding was around 500 μM Glycyrrhetinic Acid. The authors proposed that this competitive binding of Glycyrrhetinic Acid to the TPA receptor may play a role in the anti–tumor-promoting effect of Glycyrrhetinic Acid. Glycyrrhizic Acid did not show any binding affinity to the TPA receptor.

Inoue et al. (1989) found that pretreatment of a mouse ear with 1 mg/ear Glycyrrhetinic Acid inhibited TPA-induced ear edema by 81%. When 1 mg/ear Glycyrrhetinic Acid was applied after 2 μg TPA, the ear edema was reduced by 23%, compared to mouse ears that received TPA only.

Rossi et al. (1995) transplanted Erlich ascites tumor cells into healthy female Swiss mice. The mice also received oral doses of 60 mg/kg/day Glycyrrhizic Acid or 30 mg/kg/day Glycyrrhetinic Acid for 10 days before infection, 10 days after infection, or for 10 days before and 10 days after infection with the tumor cells. Control animals received the tumor infection without Glycyrrhizic Acid or Glycyrrhetinic Acid. The rate of mouse deaths was used to determine the extent of protection provided by the test materials. Pretreatment or post-treatment with either test material did not protect the mice from the lethal tumors. However, the combination of pretreatment and post-treatment of Glycyrrhizic Acid delayed the 50% mortality rate from days 15 to 18–19. Glycyrrhetinic Acid on any dose schedule tested did not affect the mortality rate.

Kelloff et al. (1994) and Wang and Nixon (2001), in review articles, state that Glycyrrhizic Acid and related compounds have been used as an herbal remedy to prevent and to treat cancer for centuries and that several animal and in vitro studies suggest that these compounds have antimutagenic, tumor-suppressive, and anticarcinogenic properties.

Agarwal et al. (1991) treated SENCAR mice with 0% or 0.05% Glycyrrhizic Acid in drinking water for 50 days. The mice were then shaved and 40 nmol DMBA was applied to the bare skin. Twenty control group and 20 Glycyrrhizic Acid—treated animals were given untreated drinking water for the remainder of the experiment. Twenty Glycyrrhizic Acid–treated mice continued to receive drinking water with 0.05% Glycyrrhizic Acid. Seven days after the DMBA application, all mice were treated with a topical dose of 4 nmol TPA twice weekly for 16 weeks. Tumors were counted.

The two Glycyrrhizic Acid groups had similar outcomes in the number of tumors produced, which was significantly fewer ($p < 0.05$) than incidence of tumors in control mice. The latent period prior to the onset of tumor appearance was later in the Glycyrrhizic Acid–treated mice than in the control mice. The authors suggested that Glycyrrhizic Acid inhibited the tumor initiation by DMBA, but not by TPA (Agarwal et al. 1991).

REPRODUCTIVE AND DEVELOPMENTAL TOXICITY

FDRL (1971b) studied the developmental toxicity potential of Ammonium Glycyrrhizate in four species of mammals. Pregnant CD-1 outbred mice received 0, 27, 90, 300, or 1000 mg/kg/day Ammonium Glycyrrhizate by oral gavage on gestation days 6 through 15 ($n = 19$ to 21 pregnant dams/dose group). The fetuses were removed by caesarian section on gestation day 17 and examined. There was no effect on maternal or fetal survival and no remarkable observation upon visceral and skeletal examinations of the fetuses.

Pregnant Wistar rats received 0, 27, 90, 300, or 1000 mg/kg/day Ammonium Glycyrrhizate by oral gavage on gestation days 6 through 15 ($n = 21$ to 22 pregnant dams/dose group). The fetuses were removed by caesarian section on gestation day 20 and examined. There was no effect on maternal or fetal survival and no remarkable observation upon visceral and skeletal examinations of the fetuses.

Pregnant golden hamsters received 0, 27, 90, 300, or 1000 mg/kg/day Ammonium Glycyrrhizate by oral gavage on gestation days 6 through 10 ($n = 21$ to 23 pregnant dams/dose group). The fetuses were removed by caesarian section on gestation day 15 and examined. There was no effect on maternal or fetal survival. Aside from dose-dependent delayed cranial ossification, no remarkable observation upon visceral and skeletal examinations of the fetuses was noted.

Pregnant Dutch-belted rabbits received 0, 27, 90, 300, or 1000 mg/kg/day Ammonium Glycyrrhizate by oral gavage on gestation days 6 through 18 ($n = 10$ to 12 pregnant dams/dose group). The fetuses were removed by caesarian section on gestation day 29 and examined. There was no effect on maternal or fetal survival and no remarkable observation upon visceral and skeletal examinations of the fetuses (FDRL 1971b).

In the previously mentioned Monlux (1974) study where rats were fed Glycyrrhizate, exposure to up to 4% Ammonium Glycyrrhizate in utero did not cause any observed developmental defects.

Mantovani et al. (1988) studied the teratogenicity of Ammonium Glycyrrhizate in Sprague-Dawley rats. Pregnant rats received drinking water containing 0, 10, 100, or 250 mg/ml Ammonium Glycyrrhizate on gestation days 7 through 17. The actual exposure levels, based on water consumption calculations, were 0, 21.33, 238.8, and 679.9 mg/kg/day, respectively. Dams were killed on gestation day 20. Dams and fetuses were examined. Water consumption was increased in dams of the 238.8 and 679.9 mg/kg/day groups. Fetuses exposed to Ammonium Glycyrrhizate did not have changes in the rate of external malformations, body weight, or degree of ossification, compared to controls. The incidence of external hemorrhages was increased in fetuses of the low- (21.33 mg/kg/day) and high- (679.9 mg/kg/day) dose groups ($p < 0.01$), but not in the middle- (238.8 mg/kg/day) dose group. Renal variants and ectopic kidneys were observed in fetuses of the lowest-dose group ($p < 0.05$). High-dose fetuses also had ectopic kidneys. Skeletal examinations revealed a dose-dependent increase in sternebral variants, significant ($p < 0.01$) in the middle- and high-dose groups. The lowest observed effect level in this study was 21.33 mg/kg/day.

Itami et al. (1985) gave pregnant Wistar rats 0%, 0.08%, 0.4%, or 2% Disodium Glycyrrhizate mixed in feed on gestation days 0 through 20 ($n = 8$ to 11 pregnant dams/dose group). There was no treatment-related effect on any of the following parameters: number of corpora lutea, number of implants, number of live fetuses, number of intrauterine dead fetuses per litter, sex ratio, fetal body weights, placental weights, degree of ossification, live birth index, survival rate, and pup body weight gain up to 8 weeks postpartum. The authors concluded that Disodium Glycyrrhizate was not teratogenic in rats under the treatment conditions of this study.

NEUROTOXICITY

Finney et al. (1958) found that 1250 mg/kg Glycyrrhetinic Acid given intraperitoneally to mice caused sedation, hypnosis, hypothermia, and respiratory depression. Glycyrrhetinic Acid given i.p. (1250 mg/kg) or subcutaneously (625 mg/kg) did not stimulate or depress either the sympathetic or parasympathetic branches of the autonomic nervous system of mice. A cat given 125 mg/kg Glycyrrhetinic Acid i.p. did not exhibit any changes in blood pressure and had normal responses to stimulation of sympathetic and parasympathetic nerves.

Sobotka et al. (1981) studied the neurobehavioral toxicity of Ammoniated Glycyrrhizin (Ammonium Glycyrrhizate) in male Sprague-Dawley rats. The rats were fed powdered diet containing 0%, 2%, 3%, or 4% Ammonium Glycyrrhizate for 4 to 6 months ($n = 40$ rats per dose group). Based on food consumption rates, the actual exposure levels were 0, 1.2, 1.9, and 2.6 mg/kg/day, respectively. Parameters evaluated included physiology (blood pressure, heart rate, temperature), motor functions (open-field exploration, Rotorod performance, general motility), and cognitive abilities (passive avoidance, active avoidance, and operant conditioning with incremental shock and incremental fixed-interval food reinforcement).

Hypertension (4% group), increased relative kidney weights (all treatment groups), decreased body weights and weight gain (4% group), bradycardia (4% group), and polydipsia (excessive thirst; 3% and 4% groups) were observed. Rectal temperatures were not affected by Ammonium Glycyrrhizate treatment. There were no treatment-related effects on motor function tests. Performance on active avoidance tests was facilitated in the 4% group, unaffected in the 3% group, and depressed in the 2% group. The authors suggested that the observations in this study are consistent with the reported hormonal effects of Ammonium Glycyrrhizate (Sobotka et al. 1981).

CLINICAL ASSESSMENT OF SAFETY

Clinical Studies

Mori et al. (1989) administered 200 to 800 mg/day Glycyrrhizic Acid to nine human immunodeficiency virus (HIV) patients (asymptomatic carrier) with hemophilia for 8 weeks. Lymphocyte counts increased in all nine patients. OKT4-positive lymphocyte numbers increased in eight patients, and the ratio of OKT4 to OKT8 cells increased in six patients. Four patients who previously had signs of liver dysfunction had clear improvements in hepatic function parameters such as serum GOT and GPT. Serum electrolytes, lipids, and protein, along with kidney function, were not affected by the Glycyrrhizic Acid.

van Gelderen et al. (2000) conducted a study using human subjects in the Netherlands to determine a no-effect level for Glycyrrhizic Acid. Thirty-nine healthy female volunteers aged 19 to 40 years and weighing 60 to 70 kg were selected after medical histories, physical examinations, and blood and urine tests. The volunteers were divided into four Glycyrrhizic Acid dose groups based on a randomized double blind treatment scheme: 0 mg/kg control ($n = 10$), 1 mg/kg/day ($n = 9$), 2 mg/kg/day ($n = 9$), and 4 mg/kg/day ($n = 11$). Glycyrrhizic Acid doses were administered orally in capsules. The experiment lasted 12 weeks: initial 2 weeks without treatment, 8 weeks of dosing with Glycyrrhizic Acid, and 2 weeks of post-treatment observations. During the 12-week period, all volunteers were required to abstain from smoking, using drugs, or using products containing Glycyrrhizic Acid. Parameters included physical examinations (at beginning and end of experimental period), questionnaire on physical condition (daily), body weight (weekly), blood pressure (weekly), edema scoring (weekly), blood potassium (weekly), blood plasma renin and aldosterone (every 2 weeks), dietary questionnaire (every 2 weeks), and blood atrial natriuretic peptide (ANP) (at weeks 8 and 10).

The aldosterone concentration and renin activity in the serum of the 4 mg/kg/day group were significantly lower ($p < 0.001$) than control after 2, 4, 6, and 8 weeks of dosing. Aldosterone levels and renin activities in the 1 and 2 mg/kg/day groups were similar to controls. The concentration of ANP was significantly decreased ($p < 0.001$) in the 4 mg/kg/day group, but not in the 1 and 2 mg/kg/day groups. Systolic and diastolic blood pressure measurements remained the same throughout the study in the 2 and 4 mg/kg/day groups but decreased slightly in the control group. Thus, relative to the control group, the 4 mg/kg/day group had significantly higher ($p = 0.018$) blood pressure than the control group. Body weight was similar between all treatment groups. Volunteers in the 4 mg/kg/day group had a significantly lower ($p < 0.01$) blood potassium concentration than those in the control group at 2 and 4 weeks into the dosing period.

In daily questionnaires of physical conditions, volunteers in the 4 mg/kg/day group described headache, nausea, vomiting, change in defecating pattern, swollen face, and tickling in the arms and legs. However, the number of complaints decreased as the study progressed.

The authors determined that the no effect level of Glycyrrhizic Acid in this study was 2 mg/kg/day. They proposed an acceptable daily intake of 0.2 mg/kg/day, using a safety factor of 10. This corresponds to 6 g of licorice per day would be safe for a 60-kg person, assuming that licorice contains 0.2% Glycyrrhizic Acid. They noted that the Dutch Nutritional Council advises a limit of 200 mg Glycyrrhizic Acid per day (van Gelderen et al. 2000).

Sigurjónsdóttir et al. (2001) demonstrated a linear dose-response relationship between Glycyrrhizic Acid and increases in blood pressure. Healthy Swedish and Icelandic volunteers aged 23 to 37 years ingested licorice amounting to 75, 270, or 540 mg/day Glycyrrhizic Acid for 2 to 4 weeks ($n = 24$, 30, or 10/dose group, respectively). After 2 weeks of dosing, mean systolic blood pressure rose 3.1, 5.2, and 14.4 mm Hg for the low-, middle-, and high-dose groups, respectively, compared to blood pressure measured prior to treatments. All rises in systolic blood pressure were statistically significant at $p$values of .03 to .000 [sic]. Increases in blood pressure were of similar magnitude after four weeks of dosing. Thus, a dose-response was demonstrated,

but a time-response was not observed. There did not seem to be a special demographic group that was especially sensitive to the effects of licorice or Glycyrrhizic Acid.

Louis and Conn (1956) administered seven normal human subjects 6 g/day Ammonium Glycyrrhizate for 3 days. Subjects maintained normal diets during the experiment. During the exposure period, renal excretion of Na^+ and Cl^- was significantly decreased, K^+ excretion was slightly increased, and water retention caused a 1.5- to 2-lb increase in body weight. Treatment also caused a reduction in excretion of Na^+ and Cl^- in thermal sweat. Withdrawal of the Ammonium Glycyrrhizate caused an immediate above-normal increase in renal excretion of Na^+ and Cl^- and retention of K^+. Body weights returned to normal five to seven days after withdrawal of Ammonium Glycyrrhizate treatment. Renal excretion of 17-ketosteroids was decreased during the exposure period, which the authors attributed to inhibited production of ACTH. Parameters of carbohydrate metabolism and protein metabolism were not affected by Ammonium Glycyrrhizate exposure.

Dermal Irritation and Sensitization

Universita' Delgi Studi Di Urbino (1990) conducted a human dermal sensitization study of an ointment containing 3% Glycyrrhetinic Acid. The subjects in this study were six male and nine female volunteers, ages 22 to 41. A 4 cm^2 occlusive pad with an unspecified amount of the ointment was applied to the skin of the arm of each volunteer. The pad remained in place for 3 days. The treatment site was scored following removal of the pad. After 7 days without treatment, the procedure was repeated, and the treatment site was examined after the second 3-day exposure. All 15 subjects had scores of "no reaction" after each treatment. The researchers concluded that the ointment (3% Glycyrrhetinic Acid) did not produce irritation or sensitization in human subjects.

Hilltop Research Inc. (1994) conducted a repeated insult patch test of a moisturizer product containing 0.3% Glycyrrhetinic Acid on 10 male and 98 female human subjects. In the induction phase, 0.15 g of the product was applied to a 2 $\times$ 2-cm area of the lateral surface of the upper arm, under an occlusive patch. Details of the protocol were not reported, but there were nine induction applications, an unspecified rest period, and a challenge patch. None of the 108 subjects had a response during the challenge phase. The authors concluded that, under the conditions of this study, there was no evidence that the test material induced a delayed contact hypersensitivity response.

Consumer Product Testing Company (2002) conducted a repeated insult patch test of Glycyrrhetinic Acid on 112 human subjects. Subjects included males and females, ranging in age from 16 to 79 years. One hundred six subjects completed the study. Those subjects who did not complete the study discontinued for reasons not related to the test material. In the induction phase, 0.2 ml of a formulation of 6% Glycyrrhetinic Acid in glycerine was applied to a 1 $\times$ 1-inch area of the scapular region under a gauze occlusive patch. Patches were applied three times per week for 3 weeks for a total of nine applications. Treatment sites were evaluated for signs of irritation 24 h after each application.

After a 2-week rest period, a challenge patch was applied to an untreated site, following the same formulation and application procedure performed in the induction phase. The challenge site was evaluated 24 and 72 h after application. None of the subjects had any sign of erythema or edema during the induction or challenge phase in this study. The authors concluded that 6% Glycyrrhetinic Acid in glycerine did not indicate a potential for dermal irritation or allergic contact sensitization (Consumer Product Testing Company 2002).

Allergisa Pesquisa Dermato-Cosmética Ltd. (2004a) conducted a human dermal sensitization study of 0.6% Glycyrrhetic Acid (also known as Glycyrrhetinic Acid). The subjects in this study were 51 females and 5 males between the ages of 18 and 66. Samples of 0.05 g/cm^2 were spread on filter paper and attached to the right or left part of the back then covered with semi-permeable hypoallergenic tape. Applications were conducted every other day, totaling 15 applications with each patch being removed after 24 h. The same was done with the saline control. After a 14-day rest period, two sample patches were applied in a fresh area. These patches were removed after 48 h of skin contact. These were scored for reaction after 30 min and 24 h. No adverse reactions were detected in the sites where the product was applied.

Allergisa Pesquisa Dermato-Cosmética Ltd. (2004b) conducted a human dermal irritation study of 0.6% Glycyhrrhetinic Acid. The subjects in this study were 52 females and 4 males between the ages of 18 and 62. Samples of 0.05 g/cm^2 were spread onto filter paper and attached to the back then covered with semipermeable hypoallergenic tape. The same was done with a control of saline. The patches were removed after 48 h and reactions were recorded after 30 min and 24 h of removal. No adverse reactions were detected in the sites where the product was applied.

Uemura (no date) used a patch test method to evaluate the skin irritation potential of 0.5% or 1.5% Stearyl Glycyrrhetinate in olive oil. The treatment sites were examined 24 h after application. There was no sign of skin irritation in any of the 89 subjects tested.

Lachartre Laboratories (1992a) evaluated the cutaneous tolerance to an eye gel containing 0.1% Glycyrrhizic Acid in 20 women. The gel was applied to the face in the area around the eyes with a soft digital massaging once or twice daily after washing for 21 days. Amounts of gel product applied ranged from 0.10 to 0.57 g per day. Each subject maintained her usual habits of makeup and hygiene, except for products similar to the test material. The eyes and the skin around the eyes were examined for signs of irritation on the 1st and 21st days of application. After the first day of application, there were no reactions. Twenty-four hours after the 20th application, two subjects had desquamation patches on the eyelids. The researchers did not think this event was related to the treatment. Eight subjects reported discomfort

sensations, as stretching. No other observations were noted. The authors concluded that repeated use of the eye gel (containing 0.1% Glycyrrhizic Acid) was well tolerated.

Lechartre Laboratories (1992b) conducted a repeated insult patch test with an eye gel containing 0.1% Glycyrrhizic Acid on 232 women, aged 18 to 62 years. In the induction phase, 0.1 ml of the test material was applied to the left shoulder of each subject, under occlusive patch, three times a week, for 3 weeks. After a 2-week period of no application, the challenge phase involved a similar application to each the induction site and a naive site. Three subjects had slight and transient erythema during the induction phase. One subject had well-defined erythema with pruritus after the first application. No other signs of irritation were reported in the induction phase. After the challenge application, one volunteer had a well-defined erythema with pruritus. No other treatment-related observations were reported.

Hilltop Research, Inc. (1995) conducted a human repeated insult patch test of an eye gel containing 0.1% Glycyrrhizic Acid on 57 male and 43 female subjects. In the induction phase, 0.1 ml of the test material was applied to a 2 × 2-cm patch pad. The pad was then applied to either the lateral surface of the upper arm or one side of the back. The pads were secured with hypoallergenic tape. Patch pads were applied for 24 h, three times per week, for 3 weeks. Twelve to 20 days after the last induction patch, a challenge patch was applied to the induction site and a naive site on the body for 24 h. The induction and challenge sites were examined 24 h after each application. The report did not give details of the study results. Six subjects had mild erythema with or without edema at the challenge phase. These observations were diminished 48 to 96 h after the challenge application and were considered irritant in nature. The authors concluded that the test material (eye gel containing 0.1% Glycyrrhizic Acid) did not produce evidence of induced contact hypersensitivity.

Quintiles (1999) conducted a human repeated insult patch test of a moisturizer containing 0.1% Glycyrrhizic Acid on 92 subjects. Induction consisted of application of 0.3 ml of the test material to the outer upper arm under occlusive patch for 24 h, three times per week, for 3 weeks. Eleven to 16 days after the last induction patch, the challenge phase involved a 24-h occluded application of the test material at the induction site and a naive site. Treatment sites were evaluated after each application. During induction, 35 subjects had moderate erythema and 42 subjects had mild erythema. There was no evidence of contact sensitization.

Phototoxicity and Photosensitization

Yamamoto (1976a) evaluated Glycyrrhizic Acid, Ammonium Glycyrrhizate, and Dipotassium Glycyrrhizate in human patch tests. In a double-blind method, the test articles (each at 5%) were applied to the forearms of 21 female volunteers for 48 h. The sites were observed for signs of irritation or inflammation. Forty-eight hours later, the dose sites were exposed to irradiation from a Dermaray Model 1 (BLB; 15 cm, 3 min), and the sites were evaluated again 48 h later. None of the exposure sites showed observable irritation reactions before or after irradiation.

Clinical Science Research International, Ltd. (CSRI) conducted a photosensitization study of an eye gel containing 0.1% Glycyrrhizic Acid in nine human subjects (CSRI 1992a). Induction treatments consisted of 24-h occluded applications of 0.2 ml of the test material, followed by UV exposure (1000-W xenon arc solar simulator) of the bare induction site. Induction treatments were performed six times over a period of 3 weeks. About 10 days after the last induction treatment, the challenge treatment consisted of a 24-h application of the test material at the induction site and two naive sites followed by exposure to 4 J/cm^2 of UVA irradiation. There was no evidence of photosensitization.

CSRI (1992b) conducted a phototoxicity study of an eye gel containing 0.1% Glycyrrhizic Acid in nine human subjects. Approximately 0.2 ml of the test material was applied to each of two circular test sites (4.5 cm^2 each) under occlusive pads for 24 h. After the application period, one of the sites was exposed to 10 J/cm^2 of UVA irradiation. The treatment sites were evaluated for up to 72 h. There was no evidence of phototoxicity to the eye gel.

Yamamoto (1976b) applied 5% Glycyrrhizic Acid, 5% Ammonium Glycyrrhizate, or 5% Dipotassium Glycyrrhizate in distilled water to the skin of 21 healthy female volunteers. The treatment area was irradiated with UV (UV dose not specified), and the irradiated treatment site was examined 48 h later. There was no sign of phototoxicity.

St. Marianna University (1995) repeated the above study (Yamamoto 1976b) and found the exact same results of no phototoxicity to 5% Glycyrrhizic Acid, 5% Ammonium Glycyrrhizate, or 5% Dipotassium Glycyrrhizate in distilled water.

Epidemiology Studies

Strandberg et al. (2001) gave questionnaires on Glycyrrhizic Acid (licorice) consumption to a sample of 1049 Finnish women with young infants. Glycyrrhizic Acid consumption was grouped into three levels: low (< 250 mg/week; $n = 751$), moderate (250–499 mg/week; $n = 145$), and heavy (≥ 500 mg/week; $n = 110$). Hospital birth records were analyzed and compared to Glycyrrhizic Acid exposure. Birth weight and maternal blood pressure were not affected by Glycyrrhizic Acid consumption. Babies with heavy exposure were significantly more likely to be born before 38 weeks ($p < 0.03$).

Case Reports

Donaldson and Duthie (1956) treated 30 patients with eczematous skin lesions with an ointment made of wool fat, liquid paraffin, and white soft paraffin with or without 2% Glycyrrhetinic Acid. There was no significant difference in the degree of healing of the lesions between the two ointment types. In this study, 2% Glycyrrhetinic Acid did not improve the condition of eczema patients.

Colin-Jones (1957) reported the results of Glycyrrhetinic Acid treatments on several cases of different skin disorders.

Treatment with 2% Glycyrrhetinic Acid in a water-miscible base markedly improved or cleared 11/13 cases of infantile eczema, 6/8 cases of flexural eczema, 3/4 cases of nummular eczema, 4/4 cases of traumatic dermatitis, 3/3 cases of dermatitis, 3/4 cases of neurodermatitis of the nape of the neck, 2/2 cases of disseminated neurodermatitis, and 3/4 cases of pruritis vulvæ et ani. Treatment with Glycyrrhetinic Acid (% not given) in 0.5% neomycin sulphate markedly improved or cleared 8/8 cases of impetigo, 2/2 cases of impetigo with associated penicillin sensitivity, 3/4 cases of impetiginized eczema, 3/4 cases of impetiginized seborrhœa, 4/5 cases of pustular psoriasis, and 2/2 cases of acne varioliformis.

Evans et al. (1958) reported the outcomes of 124 cases of various skin disorders (e.g., contact and allergic dermatitis, anogenital pruritus, and several types of eczema) after treatment with Glycyrrhetinic Acid (doses not specified). Of the 124 cases, 91 showed marked improvement or cleared, and 25 cases showed improvement. Eight of the reported cases showed no improvement. The author stated that in many cases Glycyrrhetinic Acid was more effective than hydrocortisone in the treatment of subacute, chronic, and intractable skin conditions.

Watanabe et al. (2001) described a case of a woman with chronic hepatitis C who did not initially respond to interferon therapy. She was treated with Glycyrrhizic Acid (60 ml Stronger Neo-minophagen C) three times per week for 2 years in conjunction with interferon-β therapy. After the treatment period, the patient's aminotransferase levels returned to normal, and the hepatitis virus C RNA level was negative. The authors commented that the interferon therapy was successful only after the liver function had improved with Glycyrrhizic Acid treatment.

Conn et al. (1968) reported a case of a 58-year-old man who was admitted to the University of Michigan Hospital with complaints of severe muscular weakness. Tests revealed that the patient had hypertension, hypokalemic alkalosis, suppressed renin activity, and aldosteronopenia. Chlorothiazide (0.5 g twice daily) and chlorthalidone (100 mg/day) failed to correct the hypertension. A careful history revealed that he had ingested 72 to 108 g of licorice candy daily for 6 to 7 years. The candy's manufacturer indicated that amount to contain about 0.5 g/day Ammonium Glycyrrhizate. The patient was put on a strict licorice-free diet with controlled sodium and supplements to replace lost potassium. The second day after admission, the patient began to regain muscular strength. Diuresis and weight loss began 8 days later. Aldosterone excretion was first measured on the 9th day after admission and was 0.8 μg/day, whereas renin activity was below detectable limits. On day 10, the 24-h secretion rate of aldosterone was 30.8 μg/day, compared to the normal mean rate of 109 μg/day. By 28 days after admission, the patient was recovering, with aldosterone excretion at 5.1 μg/day and renin activity at 222 μg/100 ml, values within normal range, and blood pressure was 120/80 to 130/85 mm Hg.

After recovery, the patient agreed to participate in an investigation to reproduce the clinical effects of Ammonium Glycyrrhizate. The patient was given 0.5 g every 12 h for 2 days, followed by 1 g every 12 h for 3 days, and then 2 g every 12 h for 5 days. There was a prompt increase in body weight. Serum sodium and blood pressure increased, and serum potassium steadily declined. Aldosterone excretion fell from 5.1 μg/day before dosing to 1.7 μg/day by day 4 and to 0.3 μg/day by day 9. Plasma renin activity fell from normal 222 μg/100 ml to undetectable levels by day 8. Ten months of a licorice-free diet after discharge, the patient felt generally healthy, and all aldosterone, renin, electrolyte and blood pressure parameters were normal. The data supported the investigators' suspicions that Ammonium Glycyrrhizate in the licorice candy that the patient had eaten for years caused a pseudoaldosteronism that contributed to electrolyte imbalance and hypertension. The patient's initial muscle weakness was attributed to hypokalemia (Conn et al. 1968).

EUROPEAN COMMISSION EVALUATION

The European Commission's Scientific Committee on Food (SCF) prepared an opinion on the safety of Glycyrrhizic Acid and Ammonium Glycyrrhizate in foods (SCF 2003). The opinion noted that the Committee had previously reviewed Glycyrrhizic Acid in 1991 and concluded that the data were inadequate to derive an acceptable daily intake (ADI), but they did advise that regular daily ingestion from all food products should not exceed an upper use level (UUL) of 100 mg/day.

In 2003, the SCF was asked to review new data on Glycyrrhizic Acid and to consider the safety of Ammonium Glycyrrhizate as a flavoring substance. After reviewing the new data, the SCF concluded that there is a stronger basis for the limit of 100 mg/day, but they still did not feel that the human toxicity data were sufficient to develop an ADI. The committee noted that there are subgroups of people for whom a limit of 100 mg/day may not provide sufficient protection. These groups include people with decreased 11-β-hydroxysteroid dehydrogenase-2 activity, people with prolonged gastrointestinal transit time, and people with hypertension or electrolyte-related or water homeostasis-related medical conditions (SCF 2003).

SUMMARY

This review considers the safety of specific organic compounds that may be isolated from licorice plants—Glycyrrhetinic Acid and its salts and esters, and Glyrrhizic Acid and its salts and esters used in cosmetics as considered by the Cosmetic Ingredient Review (CIR) Expert Panel. It does not address the plant extracts from the licorice plant—those will appear in a separate report.

The ingredients in this safety assessment are Glycyrrhetinic Acid, Potassium Glycyrrhetinate, Disodium Succinoyl Glycyrrhetinate, Glyceryl Glycyrrhetinate, Glycyrrhetinyl Stearate, Stearyl Glycyrrhetinate, Glycyrrhizic Acid, Ammonium Glycyrrhizate, Dipotassium Glycyrrhizate, Disodium Glycyrrhizate, Trisodium Glycyrrhizate, Methyl Glycyrrhizate, and

Potassium Glycyrrhizinate. All these compounds have the basic core structure of Glycyrrhetinic Acid with varying R groups.

These ingredients are ethanol or water soluble. Ultraviolet radiation absorption is in the UVC region. Semi-micro-HPLC, mass spectrometry, and nuclear magnetic resonance spectra have been used to detect these ingredients.

Glycyrrhetinic Acid has been found to be at least 98% pure. It has been found to contain 0.6% 24-OH-Glycyrrhetinic Acid, not more than 20 μg/g of heavy metals and not more than 2 μg/g of arsenic. No residue was detected in Glycyrrhetic Acid. Ammonium Glycyrrhizate has been found to be at least 98% pure and Dipotassium Glycyrrhizate has been found to be at least 95% pure.

Glycyrrhetinic Acid and its relatives function in cosmetics as either a flavoring agent, a skin-conditioning agent—miscellaneous or both. Glycyrrhetinic Acid is used at concentrations of up to 2%; Stearyl Glycyrrhetinate, 1%; Glycyrrhizic Acid, 0.1%; Ammonium Glycyrrhizate, 5%; Dipotassium Glycyrrhizate, 1%; and Potassium Glycyrretinate, 1%.

Glycyrrhizic Acid is poorly absorbed by the intestinal tract. However, it may be hydrolyzed by a specialized β-glucuronidase produced by intestinal bacteria into Glycyrrhetinic Acid. Glycyrrhetinic Acid and Glycyrrhizic Acid bind extensively to rat and human albumin but do not absorb well into tissues. Glycyrrhetinic Acid and Glycyrrhizic Acid and metabolites are mostly excreted in the bile and are subject to enterohepatic cycling in rats, and presumably humans. Very little is excreted in urine.

In rats given radioactive Glycyrrhetinic Acid orally, 86% of the radioactivity was recovered in 1 to 3 days with 83% in the feces, 1% in the urine and 4% remained in the liver. In rats given radioactive Glycyrrhetinic Acid subdermally, 74% of the radioactivity was recovered with 73% in the feces and 1% in the urine. Of the radioactivity recovered in the feces, only 7.4% was unchanged Glycyrretinic Acid. In humans Glycyrrhizic Acid was not detected in blood plasma after oral administration, but Glycyrrhetinic Acid was detected at $<$200 ng/ml. In the urine, 0.3% to 0.8% of the Glycyrrhizic Acid was recovered.

Dipotassium Glycyrrhizate was undetectable in the receptor chamber when tested for transepidermal permeation through pig skin.

Glycyrrhizic Acid increased the dermal penetration of diclofenac sodium in rat skin. Dipotassium Glycyrrhizate increased the intestinal absorption of calcitonin in rats. In humans, Glycyrrhetinic Acid potentiated the effects of hydrocortisone in the skin, possibly by increasing the percutaneous absorption of hydrocortisone.

Moderate chronic or high acute exposure to Glycyrrhizic Acid, Ammonium Glycyrrhizate, and their metabolites have been demonstrated to cause several transient systemic alterations including increased potassium excretion, sodium and water retention, body weight gain, alkalosis, suppression of the renin-angiotensis-aldosterone system, hypertension, and muscular paralysis. Many of these effects result from Glycyrrhizic Acid inhibition of 11β-OHSD2 in the kidney. Other enzyme activities affected include proteinases, cytochrome P450 monooxygenase, protein kinases, and tyrosinase.

Glycyrrhetinic Acid and its derivatives block gap junction intracellular communication in a dose-dependent manner in animal and human cells, including epithelial cells, fibroblasts, osteoblasts, hepatocytes, and astrocytes. At high concentrations, Glycyrrhetinic Acid is cytotoxic.

Glycyrrhetinic Acid and Glycyrrhizic Acid have been shown to protect liver tissue from known hepatotoxins such as carbon tetrachloride.

Glycyrrhizic Acid has been used to treat chronic hepatitis, inhibiting the penetration of the hepatitis A virus into hepatocytes. Other anti-viral activity included influenza, vaccinia, herpes simplex 1, Newcastle disease, and vesicular stomatitis, but not polio type 1.

Glycyrrhetinic Acid and Glycyrrhizic Acid have antiinflammatory effects in rats and mice. Other cellular effects include apoptosis and enhanced interleukin and interferon production.

The acute intraperitoneal LD_{50} for Glycyrrhetinic Acid in mice was 308 mg/kg and the oral LD_{50} was $>$610 mg/kg. The oral LD_{50} in rats was reported to be 610 mg/kg. Higher LD_{50} values were generally reported for salts.

Little short-term, subchronic, or chronic toxicity was seen in rats given ammonium, dipotassium, or disodium salts of Glycyrrhizic Acid.

Glycyrrhetinic Acid at 100 mg/ml was not irritating to shaved rabbit skin. In an in vitro irritation assay, Glycyrrhetinic Acid was considered slightly irritating.

Glycyrrhetinic Acid inhibited the mutagenic activity of benzo[a]pyrene in Ames strains TA-98 and TA-100. Glycyrrhetinic Acid inhibited DMBA and TPA tumor initiation and promotion in mice. Glycyrrhizic Acid inhibited tumor initiation by DMBA but not TPA tumor promotion in mice. Glycyrrhizic Acid delayed mortality in mice injected with Erlich ascites tumor cells, but did not reduce the mortality rate. Ammonium Glycyrrhizate was not genotoxic in in vivo and in vitro cytogenetics assays, the dominant lethal assay, Ames strain TA1530 and *Salmonella* strain G46, and heritable translocation tests, except for possible increase in dominant lethal mutations in rats given 2000 mg/kg day^{-1} in their diet. Disodium Glycyrrhizate was not carcinogenic in a mouse drinking water study at exposure levels up to 12.2 mg/kg day^{-1} for 96 weeks.

Glycyrrhizate salts produced no reproductive or developmental toxicity in rats, mice, golden hamsters, or Dutch-belted rabbits, except for a dose-dependent increase (at 238.8 and 679.9 mg/kg day^{-1}) in sternebral variants in study using rats.

Sedation, hypnosis, hypothermia, and respiratory depression were seen in mice given 1250 mg/kg Glycyrrhetinic Acid intraperitoneally. Rats fed a powdered diet containing up to 4% Ammonium Glycyrrhizate had no treatment related effects in motor function tests, but active avoidance was facilitated at 4%, unaffected at 3%, and depressed at 2%.

In a study of 39 healthy volunteers, a no effect of an oral dosage of 2 mg/kg/day was determined for Glycyrrhizic Acid. Glycyrrhizic Acid increased the lymphocyte count in HIV patients with hemophilia, and increased blood pressure in healthy individuals. Clinical tests in six normal individuals using Ammonium Glycyrrhizate at 6g/day revealed reduced renal and thermal sweat excretion of Na^+ and K^+. Carbohydrate and protein metabolism were not affected.

Glycyrrhetinic Acid at concentrations up to 6% was not an irritant or a sensitizer. Neither Glycyrrhizic Acid, Ammonium Glycyrrhizate, nor Dipotassium Glycyrrhizate at 5% was phototoxic agents or photosensitizers. One case reports linked licorice candy consumption (72 to 108 g/day) with muscular weakness, hypertension, alkalosis, suppressed renin activity, and aldosteronopenia. Various uses of these licorice ingredients in clinical treatment have also been reported.

Birth weight and maternal blood pressure were unrelated to the level of consumption of Glycyrrhizic Acid in 1049 Finnish women with infants, but babies whose mothers consumed >500 mg/wk were more likely to be born before 38 weeks.

A European Commission Scientific Committee on Food opinion did not establish an acceptable daily intake of Glycyrrhizic Acid and Ammonium Glycyrrhizate in foods, but did recommend an upper use level of 100 mg/day and identified decreased 11-β-hydroxysteroid dehydrogenase-2 activity, prolonged gastrointestinal transit time, or hypertension or electrolyte-related or water homeostasis-related medical conditions as conditions for which the upper use level may be too high.

DISCUSSION

The CIR Expert Panel noted that the ingredients in this safety assessment are not plant extracts, powders, or juices, but rather are specific chemical species that may be isolated from the licorice plant. Because these chemicals may be isolated from plant sources, however, steps should be taken to assure that pesticide and toxic metal residues are below acceptable levels. The Panel advised the industry that total polychlorobiphenyl (PCB)/pesticide contamination should be limited to not more than 40 ppm, with not more than 10 ppm for any specific residue, and that toxic metal levels must not contain more than 3 mg/kg of arsenic (as As), not more than 0.002% heavy metals, and not more than 1 mg/kg of lead (as Pb).

No published information was identified for Disodium Succinoyl Glycyrrhetinate, Glyceryl Glycyrrhetinate, Glycyrrhetinyl Stearate, Methyl Glycyrrhizate, Potassium Glycyrrhetinate, Potassium Glycyrrhizinate, or Trisodium Glycyrrhizate, but they are considered to be sufficiently structurally related to the rest of the ingredients that the data may be extrapolated to address their safety.

Although Glycyrrhizic Acid is cytotoxic at high doses and ingestion can have physiological effects, there is little acute, short-term, subchronic, or chronic toxicity and Dipotassium Glycyrrhizate is poorly absorbed through the skin. Glycyrrhizate salts were not genotoxic in all but one assay at a high exposure level, were not carcinogenic in animals tests, and inhibited tumor initiation and promotion by known tumor producing chemicals. Glycyrrhizate salts produced no reproductive or developmental toxicity in several animal species, except for one finding of sternebral variants in a rat drinking water study. Because of the poor dermal absorption, this one finding did not suggest a safety concern regarding use in cosmetic formulations.

These ingredients are not considered to be irritants, sensitizers, phototoxic agents, or photosensitizers at the current maximum concentration of use. Accordingly, the CIR Expert Panel concluded that these ingredients are safe in the current practices of use and concentration.

The Panel recognizes that certain ingredients in this group are reportedly used in a given product category, but the concentration of use is not available. For other ingredients in this group, information regarding use concentration for specific product categories is provided, but the number of such products is not known. In still other cases, an ingredient is not in current use, but may be used in the future.

Although there are gaps in knowledge about product use, the overall information available on the types of products in which these ingredients are used and at what concentration indicate a pattern of use. Within this overall pattern of use, the Expert Panel considers all ingredients in this group to be safe.

CONCLUSION

Ammonium Glycyrrhizate, Dipotassium Glycyrrhizate, Disodium Glycyrrhizate, Disodium Succinoyl Glycyrrhetinate, Glyceryl Glycyrrhetinate, Glycyrrhetinic Acid, Glycyrrhetinyl Stearate, Glycyrrhizic Acid, Methyl Glycyrrhizate, Potassium Glycyrrhetinate, Potassium Glycyrrhizinate, Stearyl Glycyrrhetinate, and Trisodium Glycyrrhizate are safe for use in cosmetic formulations in the practices of use and concentration as described in this safety assessment.

Received July 04, 2014; Revised July 14, 2014; Accepted July 21, 2014

Abstract Progressive fibrosis and cirrhosis, clinically presenting as end-stage liver disease are common outcomes in alcoholic Liver disease (ALD) patients. A variety of laboratory tests are available to assist in the progression and diagnosis of cirrhosis to end stage liver disease. The aim of this study is to identify potential novel biomarkers for progression of cirrhosis to end-stage liver cirrhosis. The biomarkers evaluated in this study included liver function indicators including serum ferritin, prothrombin time, albumin, total bilirubin, alanine aminotransferase (ALT), aspartate aminotransferase (AST), gamma-glutamyltransferase (GGT), renal parameters (urea and creatinine) and red blood cell counts, hemoglobin and blood glucose. The study included two groups based on severity of cirrhosis of liver; categorized as compensated and decompensated liver cirrhotic patients based on child Pugh criteria. All decompensated cirrhotic patients in the study group had significantly elevated biomarkers levels ($P<0.001$) than those with compensated cirrhotic patients and control group who were not suffering from liver cirrhosis. Thus these results suggest that elevated and altered liver and hematological biomarkers are associated with pathogenesis and progression of liver cirrhosis.

Keywords: *alcohol, Biochemical marker, haematological markers, γ-Glutamyltransferase, Aminotransferases*

1. Introduction

Alcoholism is condition resulting from excess drinking of beverages that contain alcohol. The major health risk of alcoholism includes liver disease, heart disease, pancreatitis, central nervous system disorders and certain forms of cancer [1]. Alcohol can be manifested in liver damage from fibrosis to end stage of cirrhosis and may eventually lead to carcinoma of liver. The liver is particularly vulnerable to disease related to heavy drinking, most commonly termed as alcoholic hepatitis or cirrhosis. The progression of alcoholic liver disease is characterized by steatosis, inflammation, necrosis and cirrohosis. When severe Cirrohosis occurs, death is the outcome [2]. Chronic consumption of alcoholic beverages is a primary cause of liver injury. Chronic and excessive consumption of alcoholic beverages provokes membrane lipid-peroxidation due to triglyceride accumulation in hepatocytes [3]. The study underway can serve as potential diagnostic tools for more specific biomarkers of ethanol-induced diseases. Hence, an attempt has been made to evaluate the effect of chronic alcohol consumption on blood, renal and hepatic biomarkers against worsening child pugh criteria.

2. Materials and Methods

2.1. Design and Subjects

A comparative study was carried out in a sample of 85 cirrhotic patients with chronic alcoholism of 31-54 years of age, and a mean consumption of ethanol 153.4 ± 36.9 g/d during the past 10 years (without alcohol ingestion in the past 30 days) and without additional diseases,

GROUP 1: (n=35)

Patients who were having with clinical, biochemical and ultrasonographic evidence of cirrhosis of liver without evidence of ascites, hepatic encephalopathy, GI bleed were classified as compensated cirrhotic patients with a mean age of 42.1 ± 10.19 years.

GROUP 2: (n=50)

Patients with clinical, biochemical, ultrasonographic evidence of cirrhosis of liver with evidence of GI bleed, hepatic encephalopathy & ascites were classified as decompensated cirrhotic patients with mean age of 42.5 ± 8.1 [4].

An equal number of aged matched normal healthy adults of with a mean age of 41.0 ± 9.4 years, with chronic alcoholism. All subjects had lived in central India for the past 10 years at the time of the study. The subjects agreed

to participate in the study after giving their informed consent.

2.2. Blood and Biochemical Analyses

Patients were obtained from gastroenterology ward of super specialty hospital with proven history of liver cirrhosis on the basis of clinical, biochemical and imaging methods and endoscopic signs. Cirrhosis was related to chronic alcohol intake. The severity of the disease was evaluated according to the Child-Pugh classification [4]. Heparin was the anticoagulant agent used. Blood samples containing heparin were analyzed using complete hemoglobin test protocol and ferritin [5,6]. The serum obtained from samples containing no anticoagulant agent was subjected to the following tests: urea, creatinine, albumin, total bilirubin, alanine aminotransferase (ALT), aspartate aminotransferase (AST), gamma-glutamyltransferase (GGT) [6-13]. All reagents employed in biochemical tests were obtained from Randox Laboratories, Ltd. These tests were used as screening measurements for diagnosis of liver injury prevalent in different stages of cirrhotic patients.

2.3. Statistical Analysis

Data were processed by use of standard statistical software Open epi. The results are presented as mean ±SD. The exact measures of associations in results between patients and control were compared using chi square test and fisher statistics. The significance was taken at $P < 0.001$.

3. Results

3.1. Effect of Alcohol on Serum Levels of Liver Chemistries.

Table 1 indicates the levels of serum bilirubin, albumin, GGT and ALT/AST ratio of compensated and decompensated cirrhotic groups as compared to that of control. The serum concentration of bilirubin was found to be significantly altered in patients with decompensation (group 2) as compared to compensated (group 1) and controls**.** The serum bilirubin levels were significantly elevated in patients consuming alcohol for the past 10 years Group 2 as compared to Group 1 and the control subjects ($P<0.001$). The albumin concentration was significantly altered in compensated and decompensated patients (group 1 & 2) as compared to control group. The serum concentration of albumin was significantly decreased ($P<0.001$) and the serum GGT Levels was significantly elevated ($P<0.001$) and gradually declined with progression of cirrhosis in patients consuming alcohol for the past 28- 45 years. Also the serum levels of ALT, AST and AST/ALT ratio was significantly altered in patients consuming alcohol with more pronounced in decompensated subjects (Group 2) as compared to control subjects.

3.2. Effect of Alcohol Intake on Renal Markers

Table 2 shows the activities of serum urea and creatinine compared to control subjects respectively. There was significant change in serum urea and creatinine levels of patients consuming alcohol for the past 10 years in decompensated (Group 2) as compared to the compensated and control subjects. The serum levels of urea and creinatine showed pronounced elevation in decompensated cirrhotic patient as compared to compensated and control subjects.

3.3. Effect of Alcohol Intake on Haemoglobin RBC Count and Serum Ferritin

Table 3 shows the level of total RBC count, Hb concentration, PT values and Serum Ferritin of control compensated and decompensated respectively as compared to that of control. The levels of total RBC count, Hb content showed depleted values against serum ferritin levels which showed steep elevation in decompensated, as against compensated and control groups. The two groups of patients (i.e. compensated and decompensated) were consuming alcohol for the past 10 years as compared to the control subjects. The prothrombin time was significantly altered in decompensated patients than in compensated and decompensated patients. The serum concentrations of cirrhotic patients were reflected according to progression and gradation of cirrhosis and significantly elevated as compared to control subjects.

Table 1. Serum ALT, AST, T.Bilirubin, Albumin, GTT levels of patients

Patients	ALT (mean±SD)	AST (mean±SD)	T.Bilurubin (mean±SD)	Albumin (mean±SD)	GGT (mean ± SD)
Control	29.18±8.23	34.04 ± 6.88	0.62 ± 0.16	3.65 ± 0.23	22.47 ± 3.30
Deompensated	79.52±14.69	132.3 ± 42.88	6.1 ± 3.22	2.70 ± 0.29	34.48 ± 19.52
Compensated	56.32±10.09	120.49 ± 29.54	1.32 ± 0.36	*3.20 ± 0.20*	44.90 ± 10.59

4. Disscusion

Excessive chronic consumption of alcohol results in profound alterations in the blood chemistries which may be associated with alterations in metabolic activities of cell resulting in several clinical and/or biochemical changes.

4.1. Effect of Chronic Alcohol Consumption on Liver Chemistries

The serum gamma glutamyl transferase (γGT), aspartate aminotransferase, bilirubin and albumin are considered to be well known markers of cirrhosis [14]. We have measured liver function tests, albumin and gamma glutamyl transferase, with worsening child Pugh classification in the present study, considering γGT as the most sensitive markers for acute hepatocellular damage. Our results revealed that levels of γGT were high in patients with severe alcoholic liver disease and low in the later stages of cirrhosis (Table 1). This pattern of rise in γ-GT levels were in congruence with the earlier study showing rise in compensated cirrhosis and fall in decompensated cirrhosis [15]. However some researches depicted controversial results [16]. The rise in the levels of γGT as also concluded by certain other studies [15] in alcoholic liver diseases may probably be due to inductive action of alcohol. Hyperbilirubinemia and hypoalbuminemia were also observed to be common features with alcoholics in our study. The decrease in serum albumin level can be attributed to nutritional status of the subjects as also reported by Das et. al. earlier [14]. Albumin has been known as a potential subject for the formation of adduct by acetaldehyde, an alcohol metabolite. Ethanol consumption also slows down the rate of hepatic protein catabolism and may be related to degree of ethanol-induced Liver injury [14]. The serum transaminases viz, aspartate aminotransferase (AST) and alanine amino-transferase (ALT) are significantly elevated in decompensated cirrhosis as compared to controls and compensated cirrhosis. The ratio of AST to ALT may help in the differential diagnosis of alcoholic liver disease. The ratio is generally 1 or less with acute liver injury [4]. Following heavy alcohol consumption there has been evidence of mitochondrial damage. In Mitochondrial damage, the elevation in ratio of mitochondrial AST to total AST (mAST: tAST) has also been reported in heavy alcohol consuming individuals. This rise is proportionately higher in alcoholic individuals than healthy individuals which contribute only 10% of mitochondrial AST activity in serum [14]. The pattern of aberration in AST and ALT observed in our study (Table 1) has been correlated well with the reports in the past [16]. Ozenirler et. al. [16] reported rise in values of ALT in decompensated cirrhosis than that of compensated cirrhosis. The values of total bilirubin as reported by Agnieszka-Szuster-Ciesieka et. al. in compensated cirrhosis showed upward trend with progression of cirrhosis [15]. The Bilirubin levels observed by us were low in compensated cirrhosis than that of decompensated cirrhosis. Ozenirler et. al. [16] showed similar pattern of bilirubin values in compensated cirrhosis. Serum albumin as reported by Agnieszka-Szuster-Ciesieka et. al. [15] and Ozenirler et. al. [16] was found to be lowered with progression from compensated to decompensated cirrhosis which matched with our study as evident from Table 1.

4.2. Effect of Chronic Alcohol Consumption on Renal Chemistries and Glucose Levels

Our present findings of kidney profile comprising slightly elevated blood urea and serum creatinine in later stages of decompensation as compared to controls and compensated cirrhosis are quite similar to earlier reports of Das et al [14]. The values of bilirubin are associated with urea and creatinine as observed by us may be used as markers in combination for diagnosis for ALD. It has been reported that liver disease has been associated with renal disorders [17]. We also have noticed hypoglycemia in patients associated with liver cirrhosis with increasing Child –Pugh score (Table 2). The finding is well supported by SQ Siler et al [18] who suggested that inhibition of gluconeogenesis and low intake of carbohydrates and other nutrients, associated with alcohol intake results in hypoglycemia.

4.3. Effect of Chronic Alcohol Consumption on Haematological Values

Alcohol has a variety of pathologic effects [17] in general including hematolological abnormalities. On hematopoiesis, it has been found that alcohol has direct action on erythroid precursors, thereby contributing to macrocytosis and the anemic state of chronic alcoholics [19]. Ethanol induces sideroblastic anemia due to interference with heme synthesis. The hematological study in the present work showed Prothrombin time (PT) elevated with increasing Child Pugh score thereby showing clear sign of liver injury (Table 3). The percentage of hemoglobin and the total number of RBC were found to be significantly decreased with heavy alcohol intake as a result of hemodilution [18]. Iqbal et. al [20] Reported decrease in hemoglobin values in decompensation which increased on liver transplantation. RBC count showed marked decrease with growing decompensation as compared to control and compensated cirrhosis (Table 3). The degree of liver impairment showed direct relation with decrease in RBC count. Das et. al [18] suggested that chronic ingestion of alcohol causes alterations in erythrocyte membrane lipids which occur with the progression of alcoholic liver disease. Thus this leads to hemolytic anemia.

In our study we also made it a point to note that with the increase in consumption of alcohol and the level of liver injury in cirrhotic patients was profoundly more severe which was evident with elevated serum transaminases levels and other biomarkers (table1,2,3).

5. Conclusion

In conclusion, it is evident from the results of this study and the existing literature that there was a compromise of Liver function system with variation in other related biomarkers of injury with respect to different organs and body systems. The two groups based on child-Pugh classification also suggested compromise of liver function with increase in alcohol consumption. The variation in

liver functions with elevated Ferretin levels and corresponding reduction in RBC'S and hemoglobin values also revealed risk to liver injury and renal functions related to excessive alcohol intake when compared with control group. Glucose levels were decreasing from control to compensated through decompensated phases reiterating the role of alcohol in glucose metabolism. Our results reemphasize the fact that with rising levels of transaminases and variation in other biomarkers of injury reflecting iron as central cofactor in producing injury, alcohol consumption and iron levels play a key role in the progression of liver disease and pathogenecity. Regular monitoring of these markers and iron overload indicators in alcoholic patients is necessary for better patient management and to minimize the morbidity and mortality related to liver injury.

Abstract

Acute alcoholic hepatitis (AAH) is a serious complication of alcohol misuse and has high short term mortality. It is a clinical syndrome characterised by jaundice and coagulopathy in a patient with a history of recent heavy alcohol use and is associated with profound immune dysfunction with a primed but ineffective immune response against pathogens. Here, we review the current knowledge of the pathogenesis and immune defects of AAH and identify areas requiring further study. Alcohol activates the immune system primarily through the disruption of gut tight junction integrity allowing the escape of pathogen-associated molecular particles (PAMPs) into the portal venous system. PAMPs stimulate cells expressing toll-like receptors (mainly myeloid derived cells) and initiate a network of intercellular signalling by secretion of many soluble mediators including cytokines and chemokines. The latter coordinates the infiltration of neutrophils, monocytes and T cells and results in hepatic stellate cell activation, cellular damage and hepatocyte death by necrosis or apoptosis. On the converse of this immune activation is the growing evidence of impaired microbial defence. Neutrophils have reduced phagocytic capacity and oxidative burst and there is recent evidence that T cell exhaustion plays a role in this.

Key words: Alcoholic hepatitis; Alcoholic liver disease; Toll-like receptors; Gut dysbiosis; T cell exhaustion

Core tip: Acute alcoholic hepatitis (AAH) has high short-term mortality and is challenging to treat with

only glucocorticoids demonstrating proven survival benefit. Development of other effective treatment requires a clear understanding of the mechanisms of immune dysfunction in AAH. Here, we review recent progress in the field and identify areas in need of further research; particularly the role of gut dysbiosis in allowing presentation of pathogen associated molecular patterns to innate receptors on myeloid cells and the subsequent recruitment of immune cell subsets. Recent data demonstrating that T cells have an exhausted phenotype and result in impaired antimicrobial defence is also discussed.

INTRODUCTION

The United Kingdom has seen an increasing burden of liver related mortality over recent decades with rates increasing 4-fold since the 1970s and 5-fold in the under-65s[1]. This is closely mirrored by the relative affordability of alcohol over this time[2], which is 61% more affordable in 2013 than 1980[3] suggesting that alcohol is an important driving factor for liver disease in the United Kingdom. However, this is not a problem unique to the United Kingdom, similar changes in alcohol consumption and alcohol related mortality have been observed in Northern and Eastern Europe[1] as well as in sub-Saharan Africa, South America and Asia[4].

Given the increasing global consumption of alcohol, it is not surprising that the incidence of acute alcoholic hepatitis (AAH), a serious complication of harmful alcohol use, has also been rising over recent years[5]. AAH is a clinical syndrome characterised by jaundice and coagulopathy in a patient with a recent history of heavy alcohol consumption[6] and has a high short term mortality of up to 40%[7]. It should be clearly differentiated from alcoholic steatohepatitis, a histological diagnosis, which can occur outside the context of current alcohol misuse[8-10].

AAH is increasingly recognised as a systemic inflammatory condition, leading to progressive organ dysfunction and the presence of a systemic inflammatory response syndrome confers a poor prognosis[9]. As well as marked immune activation, there is severe impairment of immune protection against pathogens[11,12]. The discordance between the primed state of the immune system and its failure in microbial defence is yet to be fully explained and an understanding of this dysfunction would certainly help in identifying novel therapeutic targets. To date, therapy has focused on the suppression of an activated immune system and numerous clinical trials have been conducted to evaluate immuno-modulatory (for example, glucocorticoids) or anti-inflammatory therapies [for example, tumour necrosis factor (TNF) alpha antagonists] which target systemic immune activation. Initial promising results from an open label study of infliximab[13] were not confirmed in a randomised controlled trial which was stopped due to excess mortality and infection[14]. Similarly, etanercept treatment was associated with increased mortality[15]. Pentoxifylline, a non-selective phosphodiesterase inhibitor with anti-TNF properties, has also shown no benefit either in combination with glucocorticoids[16,17] or alone[18]. To date only glucocorticoids have a proven short term survival benefit[19,20]. The challenge is how to strike the correct balance between supressing an overactive immune system without further impairing its protective role since death through sepsis remains a significant issue with immunosuppressive treatments[13,21].

The rising incidence of AAH together with its high mortality and limited treatment options has resulted in the European Association for the Study of the Liver identifying AAH as a priority area for research with a specific aim to investigate molecular signals which may predict clinical outcome[22]. Here, we review the current knowledge of the immune mechanisms involved in the pathogenesis of AAH and focus on areas in need of future study. We have not discussed the direct toxic effects on the liver of alcohol and its metabolites including oxidative stress and acetaldehyde adducts which have been reviewed in detail elsewhere[23,24].

THE GUT-LIVER AXIS

The mechanisms by which alcohol activates the immune system were first conclusively elucidated by Thurman *et al*[25] in 1999. The presence of alcohol allowed the presentation of pathogen associated molecular patterns (PAMPs) to hepatic macrophages (Kupffer cells) by modulating intestinal permeability[25]. Subsequent studies have highlighted the importance of the effects of alcohol on the gut microbiome itself with alterations in both the number and balance of organisms which contribute to the breakdown of the intestinal barrier[26]. In a murine model of alcohol related liver disease (ALD), intestinal bacterial overgrowth occurs with a corresponding reduction in probiotic species such as *Lactobacillus*[26]. In humans, bacterial overgrowth has been found in jejunal aspirates from chronic alcohol misusers[27] but the species of bacteria is also important. In a randomised controlled trial (RCT) of *Lactobacillus* and *Bifidobacterium* probiotic therapy in patients with alcoholic psychosis, baseline levels of intestinal probiotic species were lower than healthy controls and short term probiotic treatment significantly improved biochemical indices[28]. Improvement in clinical disease score has also been demonstrated in a small RCT by *Escherichia coli Nissle* treatment of patients

with stable cirrhosis[29]. There is also preliminary data that treatment with probiotics can improve neutrophil phagocytic function in stable cirrhosis with normalisation of phagocytosis after 7 d of treatment with *Lactobacillus casei Shirota*[30].

To date, the most detailed human study of the effects of alcohol on gut dysbiosis compared patients with ALD cirrhosis, patients with alcohol dependence and healthy controls using next generation sequencing techniques to analyse the 16S ribosomal RNA (rRNA)[31]. Compared to the control group a subset of patients displayed gut dysbiosis with significantly lower levels of *Bacteroides* and higher levels of *Proteobacteria*, which was associated with increased systemic endotoxin. Next generation sequencing rRNA studies have yet to be performed in patients with AAH.

Gut dysbiosis alters the intestinal lumen integrity through mechanisms that are incompletely understood. It is clear that the microbiota are key in increasing gut permeability through murine experiments in which the sterilised gut protects against alcohol-induced intestinal barrier leakage[32]. Disruption of tight junctions is probably mediated by microbial metabolism of alcohol to acetaldehyde[33]. However, systemic TNFα and IL-1β, which are increased in patients with AAH, also reduce tight junction integrity so there may be a positive feedback loop in these patients[34]. Furthermore, the loss of probiotic bacterial species may reduce barrier protection since transfer of *Lactobacillus* ameliorates ALD in a mouse model[35]. In a more acute murine model of alcoholic steatohepatitis *Lactobacillus* treatment restored intestinal integrity, reduced oxidative stress and improved histological liver damage[36].

The leaky gut seen in patients with AAH results in presentation of PAMPs to hepatic innate immune cells, particularly Kupffer cells. Chronic alcohol misusers have higher levels of endotoxin [lipopolysaccharide (LPS)] systemically[37] as well as in the portal vein[38] suggesting that there is greater exposure of the liver to microbial components. Interestingly, this defect may be rapidly reversible: in a study of alcohol dependent patients, both intestinal permeability and LPS levels were elevated compared to normal controls but returned to normality after 3 wk of abstinence[39].

Most of our understanding of gut dysbiosis in AAH comes from animal models and patients with chronic ALD. Future study should be directed at analysing the gut microbiome of patients with AAH compared to healthy controls and patients with cirrhosis. A well powered RCT should then be conducted to test the efficacy of specific probiotic therapy designed to restore the microbiome. Work in this area is underway as demonstrated by a single trial registered at Clinicaltrials.gov which is investigating 7 d of treatment with several probiotic regimes but this is not powered to detect survival differences[40]. Prevention of the disruption of gut tight junctions is also an appealing therapeutic target but this is likely to be due to a complex interplay between gut bacteria and innate immunity and a more detailed understanding of the mechanisms of disruption is first required.

TOLL-LIKE RECEPTORS

Toll-like receptors (TLRs) are innate pattern recognition receptors for a wide variety of PAMPs such as microbial components, endogenous molecules and danger signals[41]. The TLR family consists of 10 receptors principally expressed by granulocytes and cells of myeloid lineage. The net action of ligand binding is the activation of the nuclear factor kappa B (NF-κB), activating protein 1 (AP1) and interferon regulatory factor (IRF) families and rapid and robust transcription of pro-inflammatory mediators[42]. In animal models of ALD, increased expression of TLR1, 2, 4, 6, 7, 8, and 9 is reported with increased sensitivity to their respective ligands[43] while in humans, TLR2, 4 and 9 are upregulated in neutrophils from AAH patients[44] suggesting that the TLR signalling pathway is important in the pathogenesis of the disease.

LPS acting *via* TLR4 appears to be the most important interaction in the pathogenesis of AAH. Mice with non-functional mutant TLR4 are protected from alcoholic liver injury[45] as are those with inactivated Kupffer cells[46]. However, both Kupffer cells and non-bone marrow derived liver cells are involved in TLR4-mediated alcoholic liver injury shown by development of ALD in TLR4$^{-/-}$ mice transferred with wildtype bone marrow cells[47]. Furthermore, deficiency in IL-1 receptor associated kinase (IRAK)-M (the negative regulator of TLR4) conferred more severe ALD[48].

The action of LPS and other PAMPs *via* innate receptors on intrahepatic cells initiates a sequence of pro-inflammatory responses. Patients with AAH have elevated levels of pro-inflammatory cytokines mostly produced by myeloid cells including IL-1, IL-6, IL-8 and TNFα (the latter is also related to disease severity)[49-51]. This results in hepatocellular damage *via* TNF Receptor 1 and intrinsic death pathways[52]. In addition, alcohol sensitises Kupffer cells to the effects of LPS[53] and hepatic macrophages and Kupffer cells produce reactive oxygen species in response to chronic alcohol exposure or LPS[54], driving further liver damage.

The TLR system has the potential to be modulated to reduce pro-inflammatory signalling in AAH but still requires more thorough evaluation. TLR expression has been studied in detail in neutrophils from patients with AAH but blockade of the overexpressed TLRs did not result in restoration of normal neutrophil function[44]. The function of other immune subsets with high TLR expression (especially monocytes, macrophages and Kupffer cells) should also be examined.

CHEMOKINES

Stimulation of both immune and non-immune intrahepatic cells results in the secretion of an array of soluble mediators including cytokines and chemokines which co-ordinate the subsequent immune response and determine the balance between liver damage and resolution of inflammation. Chemokines and their respective receptors control the influx of leucocyte subsets into the liver and have been shown to play important roles in shaping the immune response in a variety of liver diseases[55]. Chemokines are low molecular weight proteins which bind to transmembrane receptors triggering a signalling cascade which alters integrin expression allowing interaction with endothelial adhesion molecules. The gradient of chemokine expression increases near the site of inflammation, which ensures the leucocyte is attracted to the appropriate site before migrating through the vascular endothelium.

Interest in chemokines and their receptors as therapeutic targets has increased over recent years since they can control the ingress of specific pro-inflammatory leucocyte subsets into sites of inflammation or injury. Currently, a number of clinical trials evaluating several chemokine and chemokine receptor antagonists for the treatment of inflammatory diseases including asthma, inflammatory bowel diseases and primary biliary cirrhosis have been registered at clinicaltrials.gov. In the context of AAH, many different chemokines have been implicated and the challenge is to determine which pathway to block. Neutrophils may be the most appropriate target since liver tissue from patients with AAH demonstrates a significant neutrophilic infiltration, the degree of which correlates with disease severity[56].

Ischaemic models of acute liver injury demonstrate that neutrophils are activated by TNFα, IL-1β and IL-17 and recruited by CXC chemokines such as CXCL1 (GROα) and CXCL8 (IL-8)[57]. Elevated levels of these chemokines among others have been confirmed in transcriptome microarray and PCR analysis of homogenised liver biopsy material from patients with AAH[58]. Levels of CXCL1, 5, 6 and 8 were all elevated in AAH *vs* normal liver and correlated with neutrophil infiltration and degree of portal hypertension and were associated with a poor prognosis at 90 d[58]. However, the exact role of the neutrophil in the pathogenesis of AAH is unclear[11] and the control of their entry into the liver is not fully understood. Moreover, chemokines that are known to attract neutrophils will also attract other immune cell types. CXCL1, 5, 6, and 8 specifically attract both neutrophils and monocytes which both express the relevant CXCR1 and CXCR2 receptors for these chemokines. Therefore, a clearer understanding of the complex pathways of leucocyte trafficking in AAH is required and blockade of a single component of the pathway may not translate into a clinical benefit[59].

The same transcriptome study also identified CCL20 as being the third most upregulated gene expressed in AAH liver tissue compared to controls[58]. CCL20 binds to CCR6 which is expressed on the Th17 subset of T cells as well as on hepatic stellate cells (HSCs) and $\gamma\delta$T cells and is likely to play an important role in the adaptive immune response.

TH17 CELLS

The Th17 cell subset, defined by its production of IL-17 and expression of RORγt, is derived from naïve $CD4^+$ T cells under the influence of cytokines IL-1β and IL-6[60]. As well as being important in the clearance of extracellular pathogens, it is also implicated in the pathogenesis of several autoimmune[61] and inflammatory diseases including ALD and AAH[62,63]. IL-17 enhances the inflammatory response by stimulating a wide variety of cells including monocytes, endothelial cells and fibroblasts, to secrete CXCL8, a neutrophil chemoattractant[64]. In a positive feedback loop, IL-17 also stimulates CCL20 secretion, itself a Th17 chemoattractant, with high levels of its receptor CCR6 expressed by Th17 cells[65,66].

Th17 cells have been implicated in the pathogenesis of AAH[63]. IL-17 protein in serum from patients with AAH was elevated as was peripheral $CD4^+$ T cell capacity to produce IL-17 on stimulation compared to healthy controls. In AAH liver tissue, there was an enrichment of IL-17^+ cells which were T cells and neutrophils and numbers correlated with degree of fibrosis. Furthermore, it was shown that HSCs have the IL-17 receptor and their secretion of important fibrotic mediators was dependent on IL-17[34].

The liver transcriptome study[58] suggests that in AAH, the high expression of CCL20 results in the infiltration of Th17 cells. Further work has shown that CCL20 levels correlate with clinical severity score, degree of portal hypertension and survival in patients with AAH and, using an animal model of acute on chronic ALD [mice treated with carbon tetrachloride (CCl_4), ethanol and LPS], that macrophages and HSCs are the primary source of CCL20[67]. In addition, exposure of primary HSCs *in vitro* to CCL20 promotes fibrogenesis[67].

Therefore, it is likely that CCL20 mediates hepatic inflammation and fibrosis in AAH by direct effects on HSCs and *via* recruitment of Th17 cells. The Th17 cytokine IL-22 has also been shown to be upregulated in peripheral blood of patients with AH and increased levels subsequently predicted better patient outcome[68]. Plasma IL-17 (but not IL-21 or IL-23) was also elevated compared to healthy controls but not related to outcome. Data was not presented to determine whether IL-17 and IL-22 were co-expressed so it is possible that IL-22 may be from the novel Th22 cells rather than pathogenic Th17 cells and hence may have a hepatoprotective effect. The protective

effects of IL-22 have been demonstrated in a chronic/binge ethanol feeding model where administration of exogenous IL-22 ameliorated liver injury and oxidative stress *via* a STAT3 mechanism[69]. A phase 2 clinical trial of recombinant human IL-22 is currently underway in patients with AAH.

Interestingly, a recent study extensively characterised pathogenic Th17 cells from healthy controls and then confirmed that they were enriched in the peripheral blood and inflamed gut of patients with Crohn's disease[70]. These pathogenic Th17 cells were resistant to steroid-mediated T cell suppression in terms of pro-inflammatory cytokine production and proliferation[70]. An animal model of airways inflammation has also suggested that Th17 cells are steroid resistant[71]. This has been further assessed by gene profile analysis, cytokine expression and proliferation in Th17 cells derived from patients with autoimmune uveitis as well as murine Th17 cells in an experimental model of uveitis, which were shown to be resistant to steroid treatment[72]. The latter study also demonstrated that both human Th17 cells *in vitro* and murine Th17 cells *in vivo* were selectively inhibited by the calcineurin inhibitor, ciclosporin A (CsA)[72].

The observation that Th17 cells are enriched in AAH but may be resistant to steroid treatment may help to explain why some patients do not respond clinically to steroid treatment. Further research is needed to clarify whether these cells are indeed steroid resistant in the context of AAH and whether there are different characteristics in this T cell subset between steroid responders and non-responders. As suggested by the recent *in vitro* and *in vivo* data discussed above[72], rescue therapy with CsA in patients with steroid resistant AAH may be efficacious. It is already well-established therapy for the treatment of steroid resistant acute severe ulcerative colitis albeit with significant toxicities and side-effects[73] but the risk of sepsis with such a potent immunosuppressive agent would be too high to justify a clinical trial in AAH patients unless a method to specifically target Th17 cells could be found. Alternatively, if steroid non-responders could be accurately identified, for example by the bioassay recently reported by our group[74], CsA could be selectively offered to these patients with the highest risk of death from AAH. Another perhaps less toxic approach is to prevent Th17 cell ingress to the liver with anti-CCL20 antibody, which may be particularly efficacious in patients who do not respond to steroid treatment.

T CELL EXHAUSTION

The phenomenon of a primed immune system but with failure of pathogen defence may be caused by a defect in effector cell negative regulatory signalling. Inhibitory pathways exist to maintain immune homeostasis to prevent over-activation and exhaustion of immune cells but allow appropriate clearance of pathogens and tumours. Several pathways exist; the best studied involves the cytotoxic T-lymphocyte associated protein 4 (CTLA-4) family. CTLA-4, a T cell surface receptor, by binding to the same molecules on antigen presenting cells, competitively antagonises CD28, the T cell co-stimulation receptor and prevents T cell activation[75]. Deletion of CTLA-4 in murine models leads to the development of fatal multiorgan autoimmune disease[76], probably as a result of unchecked CD28-mediated T cell stimulation, demonstrating its importance in immune control. A member of the CTLA-4 family, programmed death 1 (PD-1) serves a similar purpose to maintain balance of effector T cell function[77] while T-cell immunoglobulin and mucin domain 3 (TIM-3) also has potent inhibitory functions on both T cells and innate immune cells[78]. It has recently been proposed that inappropriate expression of PD-1 and TIM-3 plays a role in the immune paresis seen in AAH[79].

Impairment in both innate and adaptive immunity was seen in patients with AAH; poor neutrophil antimicrobial function and reduced T cell interferon-γ (IFNγ) production was demonstrated. In addition, PD-1, TIM-3 and their ligands were overexpressed on T cells from the peripheral blood of patients with AAH compared to patients with ALD or healthy controls but when these receptors were blocked the immune defect was overcome. It was shown that the overexpression of these inhibitory molecules was mediated by LPS binding to TLR4 on $CD14^+$ monocytes[79].

These intriguing data inform new paradigms of how an active immune system exposed to many PAMPs can remain impaired at pathogen clearance and suggest that gut dysbiosis is central to the pathogenesis of the disease. However, the effect of other TLR ligands, cytokines and the direct effect of alcohol on negative regulatory molecule expression (PD-1, TIM-3 and others) have not been investigated. It is important to note that this study was conducted using peripheral blood derived immune cells which may not accurately reflect what occurs within the liver and therefore a similar effect needs to be demonstrated on intrahepatic immune cell subsets. Finally, careful consideration of how to translate these findings to a possible therapy is required. Restoration of immune homeostasis involves the rebalancing of pro- and anti-inflammatory pathways. Improving host defence by blockade of these regulatory pathways may result in the tipping of the balance too far in favour of immune activation which may drive further liver damage. An experimental model of AAH should be first employed to assess whether this strategy would have a beneficial effect.

GRANULOCYTE COLONY-STIMULATING FACTOR

The cytokine granulocyte colony-stimulating factor

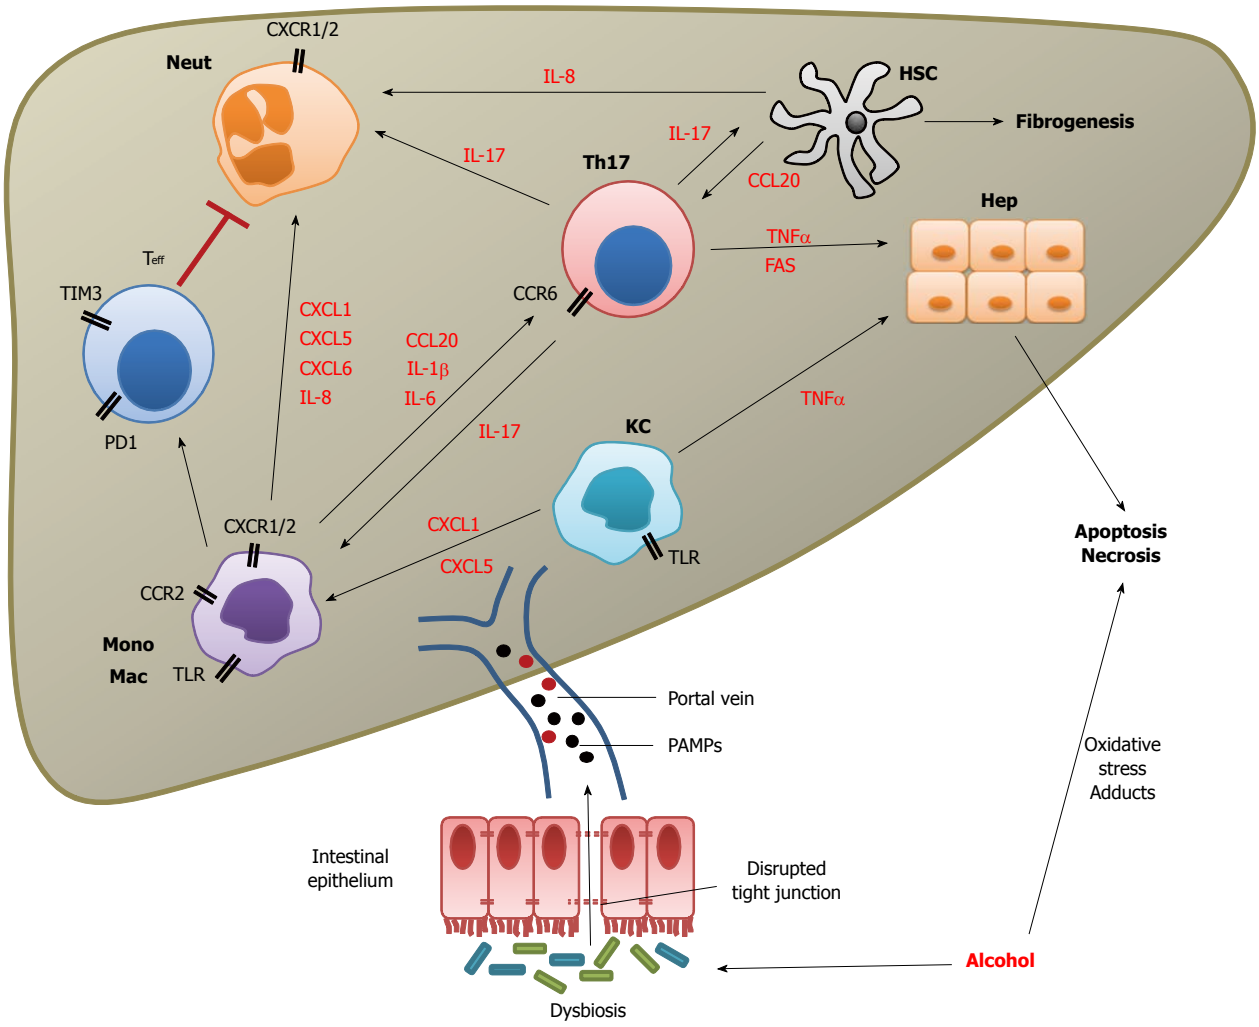

Figure 1 Immune dysfunction in acute alcoholic hepatitis. Alcohol has a direct effect on hepatocytes by production of reactive oxygen species causing oxidative stress. It also results in the production of acetaldehyde adducts which can cause DNA damage, mutagenesis and direct cell death. Alcohol consumption also leads to intestinal bacterial overgrowth and gut dysbiosis with a loss of *lactobacillus* and increase in *proteobacteria* species. Dysbiosis together with the direct effect of acetaldehyde (a metabolite of alcohol) and pro-inflammatory cytokines disrupts epithelial tight junctions and allows the escape of pathogen-associated molecular patterns (PAMPs) into the portal circulation. Within the liver PAMPs are presented to Toll-like receptors (TLRs) on myeloid cells including monocytes (Mono), macrophages (Mac) and Kupffer cells (KC) stimulating release of cytokines and chemokines. In addition, TLR4 activation on monocytes leads to upregulation of negative inhibitory molecules programmed death 1 (PD-1) and T-cell immunoglobulin and mucin domain 3 (TIM-3) on effector T cells (T_{eff}), which in turn inhibit neutrophil (Neut) anti-microbial functions. Chemokines and cytokines coordinate the infiltration and stimulation of other immune cells in particular neutrophils, monocytes (both by CXCL1, 5, 6 and IL-8) and Th17 cells (by CCL20). Th17 cells further increase neutrophil infiltration and also stimulate hepatic stellate cells (HSCs) to produce fibrogenic mediators. TNFα and Fas produced by T cells also leads to hepatocyte cell death by apoptosis through the Fas and TNF receptor pathways.

(G-CSF) stimulates bone marrow production of granulocytes and haematopoietic stem cells and is involved in the proliferation and differentiation of neutrophils but may also play a role in hepatic regeneration[80]. G-CSF treatment enhances the bactericidal and phagocytic capacity of human neutrophils from healthy subjects as well as impaired neutrophils from HIV-1 infected individuals[81]. It is therefore an appealing therapy for AAH which has the potential to both enhance neutrophil function and hepatocyte regeneration.

G-CSF was well tolerated in patients with cirrhosis and alcoholic steatohepatitis; 5 d of treatment was associated with an increase in circulating $CD34^+$ cells (a surrogate for haematopoietic stem cells), increased serum hepatocyte growth factor and proliferation of hepatic progenitor cells in day 7 liver biopsy specimens. However, there was no change in liver function compared to the control group[82]. A randomised open label trial of G-CSF treatment of Acute on Chronic Liver Failure (of which 57% had alcoholic hepatitis as the underlying aetiology) demonstrated increased hepatic $CD34^+$ cells after 28 d and significantly improved 60 d survival[83]. A recent open label RCT of 5 d of G-CSF *vs* standard care (including pentoxifylline) in the treatment of patients with AAH resulted in a greater number of serum $CD34^+$ cells and improved 3 mo survival compared to standard care[84].

These trials have demonstrated the potential benefit of G-CSF in the treatment of AAH but con-

firmation of its benefit in a large double-blind RCT is needed. Further study is required to elucidate the mechanisms of G-CSF action and evaluate its benefit in the context of steroid resistant disease.

CONCLUSION

Evidence drawn from studies on patients with AAH and chronic ALD as well as animal models has enhanced our understanding of the immune mechanisms that occur in AAH. In summary, chronic alcohol consumption leads to gut dysbiosis, disrupting the gut epithelial integrity and allowing the presentation of PAMPs to intrahepatic cells *via* the portal circulation. This in turn causes activation of a network of cells resulting in the alteration of surface molecular patterns and the release of a plethora of soluble mediators, which co-ordinates the influx of immune cells into the liver. In the context of AAH, these immune cell subsets cause direct damage to hepatocytes and stimulate HSCs to produce fibrogenic molecules leading to liver cell death and fibrosis. Additionally, there is evidence of immune paresis with poor innate cell responses and increased T cell exhaustion resulting in a reduced ability to prevent bacterial infection (Figure 1).

Many of the mechanisms of pathogenesis require confirmation and testing in patients with AAH but have the potential to yield new therapeutic targets in the future. Here, we have highlighted the gut microbiome, the expression of TLRs on different myeloid cell subsets, the chemokine pathway, the steroid responsiveness of Th17 cells, T cell exhaustion and G-CSF therapy as priority areas for further research.

Protective Effect of Magnesium Isoglycyrrhizina on Acute Hepatic Injury in Mice

DONG Liping, YU Feng, LIU Jing,MU Xianmin(Research Division of Pharmacology, China Pharmaceutical University, Nanjing 210009, China)

OBJECTIVE: To investigate the protective effect of MgIG on acute hepatic injury in mice induced by D-GalN. METHODS: The acute hepatic injury model of mice was induced by D-GalN. The mice were divided into control group, patho-model group, MgIG high and low dose group,compound glycyrrhizin group,Essentiale N group and Tiopronin group. The changes of activity of ALT, AST in serum and MDA, SOD, XOD,GSH-PX,T-AOC, NO, NOS, iNOS content in liver tissue were measured. Then by HE staining the pathologic change of liver tissue was examined under light microscope. RESULTS: MgIG could decrease(P0.01) the activities of ALT, AST in serum and MDA, XOD,NO,NOS, iNOS content in liver tissue; and increase the SOD, GSH-PX, T-AOC content in liver tissue. It was observed that MgIG could significantly alleviate the necrotic pathologic change of liver tissue. CONCLUSION: MgIG has protective function against acute liver injury in mice induced by D-GalN.

Influence of antioxidants (mannitol and allopurinol) on oxygen free radical generation during and after cardiopulmonary bypass

MICHAEL D. ENGLAND, M.S., NICHOLAS C. CAVAROCCHI, M.D., JOHN F. O'BRIEN, PH.D., EDUARDO SOLIS, M.D., JAMES R. PLUTH, M.D., THOMAS A. ORSZULAK, M.D., MICHAEL P. KAYE, M.D., AND HARTZELL V. SCHAFF, M.D.

ABSTRACT Oxygen-derived free radicals (O_2^-, H_2O_2, OH·) are produced during oxidative metabolism, ischemia and reperfusion, and cardiopulmonary bypass (CPB). When oxygen free radical production exceeds scavenging capacity, peroxidation of structural lipids in cell membranes can occur with potentially injurious consequences. In this prospective study, 45 patients were evaluated to determine the effect of CPB on oxygen free radical generation. Twenty patients in group I were controls. Exogenous oxygen free radical antioxidants were administered before bypass to patients in group II ($n = 15$, mannitol) and group III ($n = 10$, allopurinol). In group I, plasma H_2O_2 increased during extracorporeal circulation from 65 ± 6.0 to 125 ± 12 μM/ml ($p < .001$). At similar sampling intervals, plasma H_2O_2 levels were significantly lower in group II ($p < .03$) and group III ($p < .05$) when compared with those in group I. Red blood cell H_2O_2 did not change in group I or group II. White blood cell H_2O_2 levels decreased in group I ($p < .04$) and group II during CPB. (Intracellular concentrations of H_2O_2 were not obtained in group III patients.) We conclude that cytotoxic oxygen radicals are generated during CPB and that pretreatment with free radical antioxidants, mannitol or allopurinol, may minimize the free radicals available for lipid peroxidation of biomembranes.
Circulation 74(suppl III), III-134, 1986.

ELECTRON REDUCTION of molecular oxygen by cytochrome oxidase produces oxygen free radicals (O_2^-, H_2O_2, and OH·) in metabolically active cells. These toxic intermediates are also formed during ischemia and reperfusion and after cardiopulmonary bypass (CPB). Catalase, superoxide dismutase, and glutathione peroxidase are intracellular enzymes that catalyze the disproportionation of these radicals preventing peroxidation of lipid membranes.[1-3] Specifically, free radical production is greatly increased in polymorphonuclear leukocytes (PMNs) via the flavoenzyme NADPH oxidase after leukocytes have been stimulated by complement C5a fragments.[4]

Chenoweth et al.[5] and Cavarocchi et al.[6] have demonstrated that C3a and C5a complement fragments and transpulmonary sequestration of leukocytes occur during CPB. In addition, studies suggest that the C5a fragment avidly binds to neutrophils and does not freely dissociate in plasma.[7] Weissmann et al.[8] and Del Maestro et al.[9] showed that stimulated PMNs release oxygen free radicals into the extracellular space. Sacks et al.[10] have demonstrated cytotoxic reactions due to oxygen radical production occurring when leukocytes are in close approximation to endothelial cells. Significant cell damage occurred only in the presence of C5a aggregated white blood cells. Thus the complement-activated leukocytes were a source of the oxygen free radicals. These workers and others[5, 9-17] have implicated superoxides and/or their byproducts as mediators of capillary endothelial damage. These theories provide a foundation for the hypothesis that the pathophysiologic mechanism of shock lung or adult respiratory distress syndrome involves oxygen free radicals.

The work of Tate and Repine[15] suggests that hydrogen peroxide or peroxide by-products are the main species responsible for the alterations in alveolar-capillary membrane permeability. The purpose of this study was to quantitate changes in oxygen free radical production during CPB as indicated by plasma hydrogen peroxide concentrations. We also investigated the effect of exogenous oxygen free radical antioxidants on plasma hydrogen peroxide. In addition, red cell and leukocyte peroxide concentrations were determined in selected patients.

Materials and methods

This prospective trial involved 45 patients undergoing coronary artery bypass or cardiac valve replacement. Patients were placed into one of three groups: group I, 20 patients undergoing standard CPB; group II, 15 patients undergoing CPB with the addition of 12.5 g of mannitol to the pump prime; group III, 10 patients receiving 1200 mg of allopurinol preoperatively (600 mg po at 9 P.M. the night before surgery and 600 mg po at 5 A.M. on the day of surgery). Clinical characteristics of the patients are presented in table 1.

The protocol required withdrawal of five samples of 10 ml of arterial blood for assay of H_2O_2 at the following times: (1) after induction of general anesthesia but before sternotomy, (2) after 30 min of CPB, (3) immediately after CPB, (4) 10 min after infusion of protamine, and (5) after sternal closure. Plasma concentrations of H_2O_2 were corrected for hemodilution resulting from crystalloid pump prime as follows: $[H_2O_2]$ corrected = $[H_2O_2]$ measured × initial packed red cell volume/packed red cell volume during CPB.

CPB equipment consisted of a Sarnes roller pump, a Bentley BOS-10 bubble oxygenator, a Shiley CARDF, or a CARDF Plus cardiotomy reservoir and a Pall arterial filter. The extracorporeal circuit was primed with 2000 ml of crystalloid solution and 6000 U of bovine lung heparin, and whole blood was added to the prime for patients with preoperative anemia (hemoglobin < 10.0 g/dl). Before CPB, the patients were anticoagulated with bovine lung heparin administered intravenously at a dose of 350 U/kg body weight to achieve an activated clotting time in excess of 450 sec. Perfusion was maintained at a flow of 2.2 to 2.4 liters/min/m^2 and a temperature of 20° to 25° C. Hypothermic potassium cardioplegic solution (crystalloid or blood) was used during aortic cross-clamping for myocardial protection. After discontinuation of CPB, protamine (1.3 mg/100 U of heparin) was administered over 5 min to neutralize the heparin.

Plasma hydrogen peroxide assay. A hydrogen peroxide–specific assay was used in these experiments.[18] The specificity of this reaction depended on a peroxidase catalyzed oxidation reaction ($2H_2O_2$ + 4 aminoantipyrine + phenol in the presence of peroxidase form a chromogen + $4H_2$). The colored product is a quinoneimine dye with a maximum absorption at 505 nM that was measured spectrophotometrically.

Red blood cell intracellular H_2O_2 preparation. A red blood cell lysate was prepared according to a technique described by Maral et al.[19] The stable dye formed after the addition of color reagent to the red blood cell lysate was quantitated by standard colorimetric techniques.

Intracellular white blood cell H_2O_2 preparation. The leukocyte preparation was that of Percy and Brady[20] with the addition of two 45 sec "shock" treatments to eliminate residual red blood cells. In this procedure, 5% dextran and a sample of whole blood were mixed and allowed to settle at ambient temperature. The supernatant was aspirated, and the infranatant was centrifuged to obtain a button of white blood cells. These cells were then shocked by adding distilled H_2O and gently mixing for 45 sec. A solution of 1.8% NaCl was then added to stop hemolysis. After centrifugation, the supernatant was aspirated and the shock treatment was repeated. A 1:500 dilution of white cells and isotonic saline was made, and cell counts were performed with a Coulter counter. The leukocytes were then sonicated and added to the assay solution. This was allowed to react 5 min, and the product formed was measured spectrophotometrically.

Statistical analysis. A paired Students t test was used for intragroup comparisons. Analysis of variance was used to compare continuous variables between different patient groups.

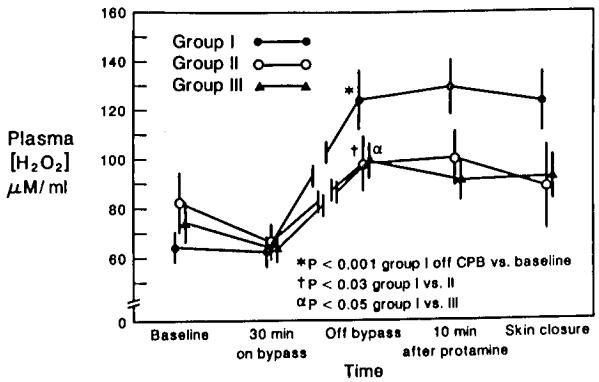

FIGURE 1. Plasma hydrogen peroxide levels during and after CPB.

Results

Plasma H_2O_2 data. The effects of CPB bypass on plasma hydrogen peroxide levels are illustrated in figure 1. Before CPB, plasma H_2O_2 levels were similar in all three groups. In control patients (group I), plasma H_2O_2 levels increased from 65 ± 6 μM/ml before CPB to 125 ± 12 μM/ml at the termination of bypass ($p < .001$). Patients in group II had a statistically nonsignificant increase in plasma H_2O_2 from 83 ± 12 μM/ml before CPB, to 99 ± 11 μM/ml at the end of CPB. In group III patients, plasma H_2O_2 was 75 ± 8 μM/ml before CPB and 100 ± 7 μM/ml after CPB ($p < .04$). The rise in H_2O_2 levels after CPB in group I was significantly greater than that in group II ($p < .03$) or group III ($p < .05$). Plasma H_2O_2 values in group III remained significantly lower than those in group I ($p < .01$) after protamine infusion and skin closure.

Leukocyte intracellular H_2O_2. In group I (control) the hydrogen peroxide concentration in leukocytes decreased from an initial level of 18 ± 1 μM/10^{10} cells to a postbypass value of 15 ± 1 μM/10^{10} cells ($p < .04$) (figure 2). There were no significant changes in H_2O_2 when comparing postprotamine (15 ± 1) and skin closure values (16 ± 1) with the post-CPB (15 ± 1)

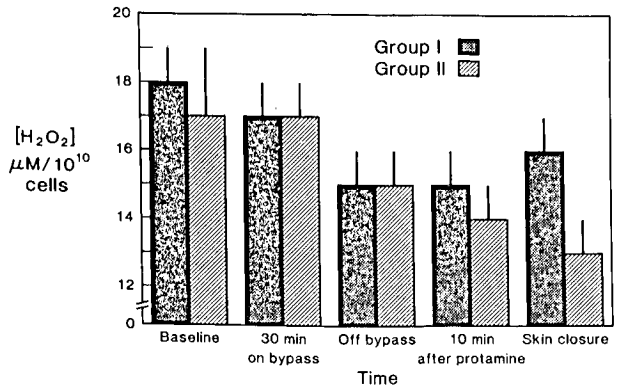

FIGURE 2. Leukocyte intracellular hydrogen peroxide levels during and after CPB.

levels. Leukocyte H_2O_2 in group II (mannitol) decreased from 17 ± 2 to 15 ± 1 $\mu M/10^{10}$ cells (p = NS). There were no significant differences when comparing postprotamine (14 ± 1) and post–sternal closure values (13 ± 1) with the immediately post-CPB value (15 ± 1). Leukocyte intracellular H_2O_2 was not measured in group III patients.

Red blood cell intracellular H_2O_2. In group I, intracellular H_2O_2 decreased from 123 ± 14 to 102 ± 7 μM/ml lysed packed red blood cells during CPB (figure 3). After extracorporeal circulation, red blood cell H_2O_2 did not change but remained significantly lower than values observed in group II ($p < .05$). The intracellular H_2O_2 concentrations were not ascertained in group III patients.

Discussion

Pulmonary gas transport mechanisms are often impaired after extracorporeal circulation, and there are several possible mechanisms. One possible mechanism that has been proposed is increased permeability of the pulmonary capillary membrane. Hydrogen peroxide, superoxide, and hydroxyl radicals have been implicated in this phenomenon.[11-16] The source of these toxic radicals appears to be PMNs and macrophages.[21-25] It is known that PMNs go through a hypermetabolic phase (oxygen burst) after being stimulated by C5a or bacteria,[4, 26] causing a transient increase in oxygen free radical production. Chenoweth et al.[5] and Cavarocchi et al.[6] have documented complement activation and transpulmonary leukosequestration during CPB.

In this study of patients undergoing extracorporeal circulation, we found significant elevations in plasma H_2O_2 after bypass. Hydrogen peroxide is a good marker for oxygen free radical production because of its stoichiometric relationship (2.1:1.0) to O_2^- and its comparative stability relative to superoxide.[27] The plasma elevations of H_2O_2 observed in our studies are greater than the steady-state levels reported by Chance et al.[1] Our data support the theory that increased oxygen free radical generation participates in the pathophysiology of extracorporeal circulation, but the study does not specifically correlate plasma H_2O_2 accumulation and pulmonary injury.

Our study demonstrates that the addition of mannitol to the pump priming solution retards the rise in plasma H_2O_2 levels observed at the conclusion of CPB. We attribute this effect to the following: first, H_2O_2 spontaneously forms hydroxyl radicals via the Haber-Weiss reaction[8, 28] ($O_2^- + H_2O_2 \rightarrow O_2 + OH^- + OH\cdot$), and second, mannitol scavenges $OH\cdot$ by forming a mannitol radical ($MH_2 + OH\cdot \rightarrow MH + H_2O$) that undergoes disproportionation or dimerizes. Theoretically, by mass action, H_2O_2 is decreased secondary to $OH\cdot$depletion. The finding that plasma levels of H_2O_2 were slightly increased (although not statistically significant) over baseline values may indicate incomplete scavenging at the mannitol dose given in this study.

Allopurinol also decreased plasma H_2O_2 levels when compared with control. The usefulness of this agent in preventing postischemic injury has been investigated by many workers.[29-33] It is generally believed that during ischemia ATP is broken down to inosine and then to hypoxanthine. Under anaerobic conditions, xanthine dehydrogenase is also converted to xanthine oxidase. During reoxygenation, hypoxanthine + O_2 in the presence of xanthine oxidase form xanthine, O_2^-, H_2O_2, and $OH\cdot$. Allopurinol is a xanthine oxidase inhibitor that blocks this reaction. The finding that plasma H_2O_2 was significantly decreased compared with control suggests that this pathway is a major source for toxic oxygen radical production during CPB. The demonstration that even with pretreatment with allopurinol H_2O_2 rose from 75 ± 8 to 100 ± 7 μM/ml ($p < .04$) suggests that the NADPH oxidase, glucose oxidase, aldehyde oxidase, and cytochrome oxygenase

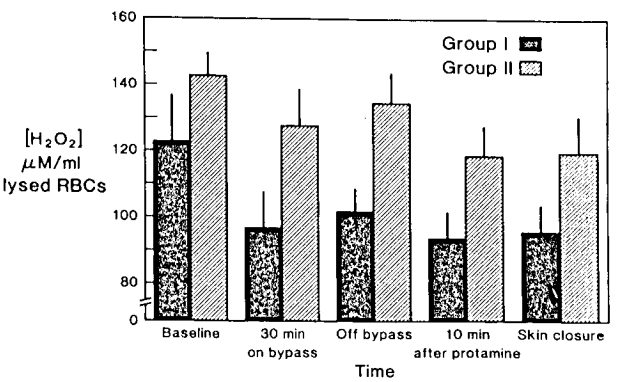

FIGURE 3. Red blood cell intracellular H_2O_2 during and after CPB.

systems contribute to the final plasma peroxide concentration.

PMN intracellular H_2O_2 levels decreased in control and in mannitol-treated patients. It is thought that toxic radicals can diffuse across cell membranes according to concentration gradients and high lipid permeability.[1] Our results reflect steady-state concentrations and not the transient oxygen burst phenomenon. The fact that both treated (group II) and nontreated (group I) groups had similar progressive declines in H_2O_2 supports the hypothesis that mannitol works on extracellular scavenging and does not affect production. The significance of this finding will require further investigation with more direct and sensitive assays for free radical production.

It is known that red blood cells contain substantial concentrations of catalase and superoxide dismutase and that these enzymes protect the cell from toxic oxidative processes. In mannitol-treated patients in whom plasma H_2O_2 rose only slightly during CPB, red blood cell H_2O_2 during and after CPB decreased only slightly. Additional study will be necessary to correlate changes in red blood cell intracellular H_2O_2 and plasma H_2O_2.

In summary, this study documents that CPB causes an increase in oxygen free radicals in plasma. The oxygen free radical antioxidants, mannitol and allopurinol, appear to reduce plasma hydrogen peroxide concentrations in patients after CPB and may be useful in reducing the risks of postperfusion sequelae such as increased capillary permeability by removing these toxic intermediates from plasma.

Received 27 June 2002; received in revised form 27 September 2002; accepted 29 November 2002

Abstract

Intravenous administration of glycyrrhizin has potential efficacy on decreasing serum aminotransferase levels in patients with chronic hepatitis. However, patients receiving this treatment are recommended to attend hospital regularly for several years. To improve the quality of life for these patients, we developed a glycyrrhizin suppository. In this pilot study, we examined the most effective and safe material contents of the suppository and revealed clinical efficacy for patients with biopsy-proven chronic hepatitis C comparing intravenous administration of glycyrrhizin. As content combinations of the suppository, a mixture of 300 mg of glycyrrhizinic ammonium salt and 60 μg of sodium capric acid, with pH neutralization, was confirmed to be most effective and safe condition, based on analysis of serum glycyrrhizin levels and the grade of rectal irritations in tested patients. The efficacy on decreasing serum alanine aminotransferase levels for 12-week administration of the suppository in 13 patients with chronic hepatitis C was similar to that in another 13 patients intravenously administered glycyrrhizin. Moreover, no serious side effects were observed. In conclusion, the usage of the newly developed suppository of glycyrrhizin can improve the quality of life for chronic hepatitis C patients, especially those who do not respond with viral clearance to interferon therapy. Using this suppository, larger and longer-term studies are needed.

Keywords: Glycyrrhizin suppository; Chronic hepatitis C; Quality of life

1. Introduction

Studies conducted in Western countries patients who acquired hepatitis C virus (HCV) by blood transfusion 15–25 years previously, suggested that 20–30% of them have progressed to liver cirrhosis, including 5–10% with end stage liver disease and 4–8% who died of liver-related causes [1,2]. In the Japanese population too, the incidence of HCV-positive patients with hepatocellular carcinoma has increased [3].

To prevent developing liver cirrhosis and hepatocellular carcinoma for patients with chronic hepatitis C, anti-viral therapies have recently been developed such as interferon and its combination with ribavirin [4–6]. However, totally sufficient effects have still not been obtained regardless of such anti-viral therapies. Therefore, different treatment strategies are required for those who do not respond. As one of these agents, an anti-inflammatory agent, intravenous administration of stronger neo-minophagen C™ (SNMC, Minophagen Pharmaceutical, Tokyo, Japan), which mainly consists of glycyrrhizin (GL), has potential efficacy for decreasing aminotransferase levels in patients with chronic hepatitis [7–12]. However, patients receiving SNMC are recommended to attend hospital regularly at least three times per week for several years. Most chronic hepatitis patients are asymptomatic. To improve the

quality of life for these patients, we developed a GL suppository.

In this pilot study, we developed the most effective and safe contents of the suppository, and estimated the clinical efficacy of the GL suppository comparing with intravenous administration of SNMC.

2. Materials and methods

2.1. Development of GL suppository

Glycyrrhizinic ammonium salt was used as a major substrate of the GL suppository. In addition, sodium capric acid was used as a promoting absorbent. Various dosage combinations of the two materials were prepared and the efficacy compared by analysis of the serum GL levels in three patients receiving each suppository. Considering drug-delivery systems, the effects of pH neutralizing treatment were evaluated. Rectal irritation for patients receiving the suppository was evaluated according to three degrees as follows: mild as a slight irritation, moderate as an intermediate irritation, and severe as an unbearable irritation.

2.2. Determination of the serum GL level

The serum GL level was determined by semi-micro high-performance liquid chromatography (HPLC) according to a previously described method [13]. Sera were collected 1 h after the administration after obtaining the patients' informed consent, and were stored at -70 °C until the assays were conducted.

2.3. Patients and therapeutic protocol

Twenty-six patients with biopsy-proven chronic hepatitis C in the Self-Defense Forces Central Hospital (Tokyo) were subjected in this study. All patients were positive for anti-HCV antibody and HCV RNA. These patients were randomly assigned into two groups by means of sealed, opaque, numbered envelopes: 13 patients received two pieces of GL suppository per day and the remaining other 13 patients were intravenously administered 40 ml SNMC (containing 80 mg of GL) per day, after obtaining the patients' informed consent. No significant differences in mean age, gender distribution, mean alanine aminotransferase (ALT) level, HCV RNA load, variations of HCV genotype, or pathological diagnosis adopted prior treatments were found between the two groups (Table 1). HCV RNA and HCV genotype were determined by conventional PCR and sequence specific priming-PCR (SSP-PCR). Pathological diagnosis was performed according to Ludwig's classification [14]. The therapeutic periods in both groups were set at 12 weeks. Subsequently, the frequencies of the major presenting side effects such as hypernatremia, hypokalemia, hypertension, and myopathy were compared.

All procedures in this study were performed with the approval of the local ethical committee and conducted under strict informed consents.

2.4. Statistic analysis

The findings in the two groups were compared using the χ^2-test and Welch's t-test (two-tail). P values < 0.05 were considered significant.

3. Results

3.1. Serum GL levels under various conditions

Considering the efficacy and drug-delivery system, we compared mean serum GL levels in tested each three patients under various concentrations of sodium capric acid and GL in the suppository. First, the concentrations of sodium capric acid in the suppository varied from 40 to 80 μg under the same GL concentration (200 mg). As shown in Fig. 1A, the mean serum GL level in patients treated with a suppository with 80 μg of sodium capric acid was the highest, however, it could not be clinically used because severe irritation to the rectal mucous membrane was observed. Therefore, we decided to set the concentration of sodium capric acid of 60 μg in the suppositories.

Secondly, the concentrations of GL ammonium salt in the suppositories varied between 200 and 400 mg under the same sodium capric acid concentration (60 μg). As shown in Fig. 1B, the mean serum GL levels in patients treated with suppositories including 300 and 400 mg of GL were the highest, however, suppositories including 400 mg GL could not be clinically used because irritation to the rectal mucous membrane was severe. Therefore, we decided to set the GL concentrations at 300 mg in the suppositories.

Finally, the effects on pH neutralization to reduce irritation to the rectal mucous membrane were evaluated. Mean serum GL levels in tested patients with the two suppositories were compared with and without the treatment of pH neutralization. As shown in Fig. 1C, the mean serum GL level in the patient receiving the suppository with the treatment of pH neutralization was higher than that without the treatment. Therefore, we decided to treat pH neutralization.

Taken together, we decided the new suppository should show the following conditions: 60 μg of sodium capric acid, 300 mg of GL, and with pH neutralization treatment.

Table 1
Profiles of the study patients with chronic hepatitis C

	Suppository	SNMC	*P*
No. of patients	13	13	
Male:female	6:7	7:6	ns
Mean age (years old)[a]	59.1±4.6	60.5±4.7	ns
Mean AST (IU/L)[a]	102.2±13.7	79.0±8.9	ns
Mean ALT (IU/L)[a]	138.8±20.3	109.5±15.0	ns
Mean HCV RNA load (kcopies/ml)	302±56	341±59	ns
HCV genotype (Ib:Iia)	11:2	10:3	ns
Pathological diagnosis[b] (moderate CAH: severe CAH)	8:5	5:8	ns

All data were adopted prior to treatment. ns, not significantly different. CAH, chronic active hepatitis.
[a] Values are expressed as mean±SEM.
[b] Pathological diagnosis was performed according to Ludwig's classification [14].

3.2. Clinical study

Using this GL suppository, we compared the decreases in the serum ALT levels with SNMC treated patients (suppository vs. SNMC). As shown in Fig. 2A, in both groups, ALT levels at 4, 8, and 12 weeks of administration in both groups were significantly decreased compared with each prior level. However, the ALT levels re-elevated 4 weeks after the end of the administrations. As shown in Fig. 2B, the decreasing ratios of the serum ALT levels during the administration periods were similar between the two groups. There were no patients showing the clearance of serum HCV RNA during the therapies in both groups.

The frequencies of the presenting side effects were compared between the two therapeutic groups. However, no significant differences were observed (Table 2).

4. Discussion

In Japan, SNMC has been empirically used for the treatment of chronic hepatitis since 1950s [7]. In 1983, Suzuki et al. first demonstrated the efficacy of SNMC on biochemical tests in chronic hepatitis using a double-blind control study [8]. Hino et al. also found an improvement in liver histology after treating chronic active hepatitis (CAH) with SNMC [15]. Recently, several studies on the efficacy of SNMC for patients with chronic hepatitis have also been reported from European and Asian countries [9–11]. As discussed above, regular intravenous administration for long periods limits the quality of life of patients. On the other hand, oral GL tablets have been used for these patients, although the biochemical improvements on the orally administered GL was lower than that of intrave-

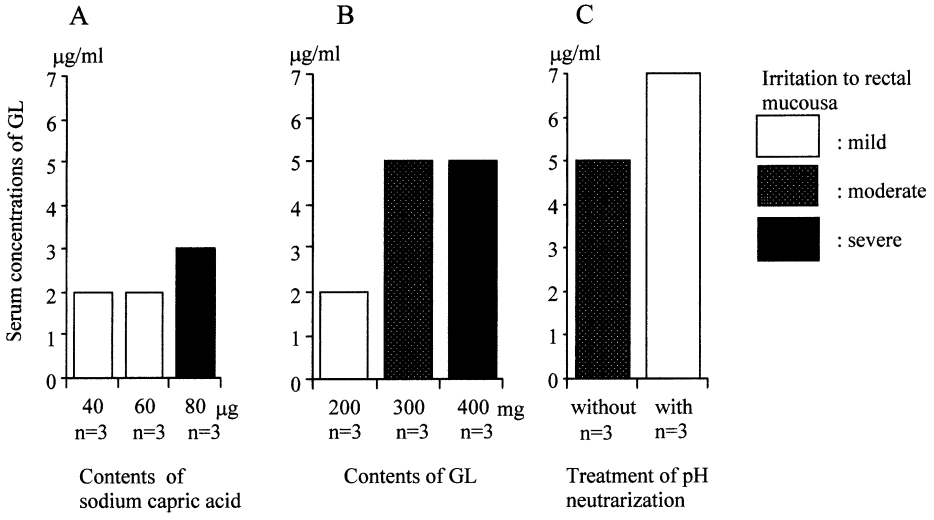

Fig. 1. Mean serum GL levels and the severity of rectal irritation in three patients receiving various doses and conditions of suppositories: (A) the concentration of sodium capric acid varied between 40 and 80 μg; (B) the concentration of GL varied between 200 and 400 mg; (C) with or without pH neutralization. The grades of rectal irritation were revealed as mild (opened bar), moderate (dotted bar), or severe (closed bar).

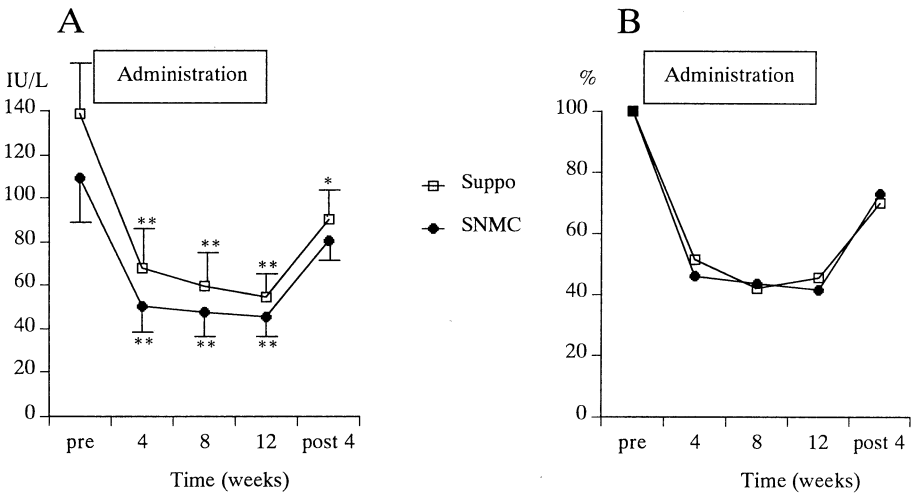

Fig. 2. Changes in the serum ALT levels in the two patient groups (suppository [opened square] and SNMC [closed circle]). (A) Changes of serum ALT levels (mean ± SEM) at each week of administration. (B) Decreasing ratios of the serum ALT levels (each prior level: 100%). $^{**}P < 0.01$, $^{*}P < 0.05$.

nously administered SNMC [16]. Moreover, pseudoaldosteronism such as hypokalemia and myopathy [17,18] in orally administered patients develops more frequently, because orally administered GL alternates 3-monoglucuronyl-glycyrrhetinic acid (GA), which was reported to be a major metabolite causing GL-induced pseudoaldosteronism [19]. Thus, oral administration of GL did not fully improve the quality of life for the patients with chronic hepatitis.

In the present study, we first succeeded in developing an effective and safe GL suppository. Considering the efficacy and the drug-delivery system, we set the conditions of the suppository materials at 60 μg of sodium capric acid, 300 mg of GL, and with pH neutralization. Using this suppository, we investigated the clinical efficacy and side effects in patients with chronic hepatitis C.

We previously reported that serial serum GL levels in patients receiving suppository (300 mg of GL) were not so high comparing those in patients receiving SNMC (40 ml). However, serial serum GA levels in patients receiving GL suppository were almost same as those in patients receiving SNMC [20]. Analysis of serum GA levels, in addition to serum GL, may implicate the dynamic kinetics in administered GL, including portal flow and intestinal re-absorption.

Table 2
Frequencies of the presenting side effects in the two patient groups

	Suppository ($n = 13$)	SNMC ($n = 13$)
Hypernatremia	0	0
Hypokalemia	0	0
Hypertension	0	0
Myopathy	0	0
Others	0	0

The present results suggested that the efficacy of the GL suppository was similar to that of 40 ml intravenously administered SNMC. Furthermore, no serious side effects were observed. Thus, it is suggested that these clinical results may greatly contribute to improve the quality of life of these patients because therapeutic choices can be widened.

In vitro GL has anti-viral activity against herpes simplex virus [21] and hepatitis A virus [22]. However, it is unlikely that GL induces viral clearance in chronic hepatitis C [9,10], because ALT rises directly after cessation of the treatment as shown in this study. It is important to define the changes in HCV RNA load in patients receiving GL for long-term period.

GL administered by suppository is considered to react directly with hepatic cells through portal circulation. On the other hand, intravenously administered GL reacts indirectly via systemic circulation [23,24]. Therefore, the reacting effect on hepatic cells of GL administered by suppository should be higher than that by intravenous administration. However, since it was reported that GL is metabolized to glycyrrhetinic acid by intestinal bacteria containing β-D-glucuronidase [25], further pharmacokinetic studies are needed using the GL suppository.

Recently, it was reported that long-term administration of SNMC for patients with chronic hepatitis C prevented developing liver cirrhosis and hepatocellular carcinoma [26,27]. Therefore, larger and longer-term studies are needed to evaluate the efficacy of the newly developed GL suppository for these patients, especially for those who do not respond with viral clearance to interferon therapy.

Glycyrrhizic acid/Pulse radiolysis/Radiation protection/Plasmid DNA/DNA strand breaks/Comet assay

Gamma-radiation induced strand breaks in plasmid pBR322 DNA. Glycyrrhizic acid (GZA) protected plasmid DNA from radiation-induced strand breaks, as the disappearance of super-coiled (ccc) form was prevented by the compound with a dose-reduction factor of 2.04 at 2.5 mM concentration. Studies of comet assay on human peripheral blood leukocytes exposed to gamma radiation in the presence and absence of glycyrrhizic acid ex vivo revealed that this compound protected the cellular DNA from radiation-induced strand breaks in a concentration-dependent manner. An intraperitoneal administration of the GZA to mice one hour before exposure to gamma radiation protected cellular DNA from radiation-induced strand breaks in peripheral blood leucocytes and bone marrow cells, as revealed by comet assay. Pulse radiolysis studies indicated that glycyrrhizic acid offered radioprotection by scavenging free radicals. The rate constants for the reaction of glycyrrhizic acid with $OH^{\cdot}$ and e_{aq}^{-} are $1.2 \times 10^{10}\ M^{-1}\ s^{-1}$ and $3.9 \times 10^{9}\ M^{-1}\ s^{-1}$, respectively.

INTRODUCTION

Root extracts of the plant *Glycyrrhiza glabra* L., known as *Yashtimadhu,* in Ayurveda have been used for curing various diseases because of its antiinflammatory, antibacterial, antiviral, and immune-modulating activities[1]. The extract, generally called liquorices, is widely used as a sweetener in food products and chewing tobacco. The active compounds of the extract have been reported to have immuno-modulating[2] antioxidant[3,4]. Our earlier studies have revealed the radio protective effect of the extract on gamma radiation induced DNA and membrane damages[5]. One major component of the extract is glycyrrhizic acid (Scheme I and its absorption spectra in Fig. 1). In biological systems, most of the damage induced by gamma rays is indirect and mediated through free radicals that interact with important macromolecules, including DNA and membranes[6,7]. Membrane damage occurs mainly because of the peroxidation of membrane lipids. In the present study we have investigated the mechanism of radiation protection of DNA by glycyrrhizic acid (GZA) *in vitro*, ex-vivo, and in vivo. The effect of GZA on the production of gamma radiation induced strand breaks in plasmid pBR322 DNA in vitro was monitored by agarose gel electrophoresis from the disappearance of supercoiled form (ccc) of DNA. The radiation-induced strand breaks in cellular DNA of human peripheral blood leukocytes was examined in ex vivo studies by the use of alkaline comet assay. Studies on in vivo radioprotection of DNA were undertaken in mice by an ip administration of GZA before whole-body irradiation and measuring strand breaks in the cellular DNA of peripheral blood leukocytes and bone mar-

row cells by alkaline comet assay. To understand the molecular mechanisms of radioprotection by GZA, the bimolecular rate constants for the reactions of primary radicals of water radiolysis with GZA were determined with the pulse radiolysis technique.

MATERIALS AND METHODS

Reagents

Plasmid pBR322 DNA was purchased from Bangalore Genei, Bangalore, India. Glycyrrhizic acid, propidium iodide, and ethylenediaminetetraacetic acid were obtained from Sigma Chemical Co., USA. Other reagents were of analytical grade obtained from local manufacturers.

Collection of human blood

Human blood samples were collected from three healthy nonsmoking volunteers, having a mean age of 25 ± 2 years, by the finger prick method and stored in heparinized eppendorf tubes at ice temperature.

Animals

Male Swiss mice, 8–10 weeks old and weighing 20–25 g each, were selected from an inbred group maintained under standard conditions of temperature (25 ± 2°C) and humidity, with a 12-hour light and 12-hour dark cycle. The animals were provided with food and water ad libitum. Usually four animals were housed in each sterile polypropylene cage containing a sterile paddy as bedding. All animal experiments were conducted with strict adherence to the ethical guidelines laid down by the Committee for the Purpose of Control and Supervision of Experiments on Animals (CPCSEA) constituted by the Animal Welfare Division of the Government of India on the use of animals in scientific research.

Gamma irradiation

Plasmid pBR322 DNA (20–25 μg/ml) in 0.1M sodium phosphate buffer pH 7.0 was exposed to ^{60}Co-gamma rays in a Gamma Cell 220 (AECL, Canada) at a dose rate of 9.6 Gy per min in the presence and absence of GZA. For in vivo experiments, the animals after ip administration of GZA (4 mg / kg body weight in double distilled water) were kept in a well-ventilated, acrylic box and whole-body exposed to 4 Gy in a Junior Theratron unit (AECL, Canada) having a dose rate of approximately 0.5 Gy/min. Ex vivo irradiation of human peripheral leukocytes in the presence and absence of glycyrrhizic acid was also done in the Junior Theratron unit.

Effect of glycyrrhizic acid on radiation-induced DNA damage in blood leukocytes and bone marrow cells

The animals were divided into the following groups:
(1) DDW+ sham irradiation
(2) DDW+ 4 Gy irradiation
(3) Glycyrrhizic acid + sham irradiation
(4) Glycyrrhizic acid + 4 Gy irradiation

One hour after the administration of DDW or GZA, animals were whole-body exposed to 0 (sham-irradiation) or 4 Gy by use of the Junior Theratron unit in a well-ventilated acrylic box. After irradiation, all four groups of were kept back in a polycarbonate cage. All animals were sacrificed by cervical dislocation after two hours of irradiation. Blood was collected in heparinized eppendorf tubes by heart puncture, and bone marrow cells were collected from the femurs[8] in ice-chilled 10 mM potassium phosphate buffer, pH 7.4.

Analysis of DNA damage

Radiation-induced damage to plasmid DNA was determined by elctrophoresis in 1% agarose gel[9,10]. The ethidium bromide stained DNA bands were analyzed by the use of Syngene software.

Measurement of DNA damage by the use of Single-Cell Gel Electrophoresis (Comet Assay)

The DNA strand breaks in the bone marrow cells and blood leukocytes were measured by the use of single-cell gel electrophoresis (comet assay) based on the method of Singh *et al.* 2000[11], with some modification[8,12,13]. Fully frosted microscope slides (Gold Coin, Mumbai) were covered with 200 μl of 1% normal melting agarose (NMA) in PBS at 45°C, immediately cover –slipped and kept at 4±°C for 10 min to allow the agarose to solidify. The removal of the cover slip from the agarose layer was followed by an addition of a second layer of 200 μl of 0.5% low-melting agarose (LMA) containing approximately 10^5 cells at 37°C. Cover slips were placed immediately, and the slides were placed at 4°C. After a solidification of the LMA, the cover slips were removed and the slides were placed in the chilled lysing solution consisting of 2.5 M NaCl, 100 mM Na_2-EDTA, 10 mM Tris-HCl, pH 10, 1% DMSO, 1% Triton-X100, and 1%

sodium sarcosinate for 1 hour at 4°C. The slides were removed from the lysing solution and placed on a horizontal electrophoresis tank filled with freshly prepared alkaline buffer (300 mM NaOH, 1 mM Na_2-EDTA, and 0.2% DMSO, pH ≥13.0). The slides were equilibrated in the same buffer for 20 min, and electrophoresis was carried out at 40 V, 350 mA for 15 min. After electrophoresis, the slides were washed gently with 0.4 M Tris-HCl buffer, pH 7.4, to remove the alkali. They were stained with propidium iodide and visualized with a fluorescent microscope (Carl Ziess Axioskop) with bright field phase contrast and an epifluorescence facility attached to a high-performance JVG TK 1280E camera. The integral frame grabber used in this system (Cvfbo1p) is a PC-based card, and it accepts color composite video output of the camera. Fifty cells/slide were captured. The quantification of the DNA strand breaks of the stored images was done with CASP software[14], by which a percent of DNA in the tail, tail migration, tail moment, and Olive tail moment could be obtained directly.

Pulse Radiolysis studies

Pulse radiolysis studies were carried out by irradiating solutions in rectangular quartz cells. The pulse radiolysis setup consists of an electron linear accelerator (Viritech Ltd., U.K.) capable of giving single shots of 50 or 500 ns or 2 μs of 7 MeV electron pulses. The pulse irradiates the sample contained in a 1 cm × 1 cm suprasil quartz cuvette kept about 12 cm from the electron beam window, where the beam diameter is approximately 1 cm. The transient changes in the absorbance of the solution caused by the electron pulse are monitored with the help of a collimated light beam from a 450 W xenon arc lamp. The output from the PMT is fed through a DC offset circuit to the Y input of an L & T storage scope that can transfer 400 mega- samples/sec on each input channel at a 250 ns/div time base range with a sensitivity of 2mV/div and having a bandwidth of 100 MHz. However, further details of the LINAC can be seen elsewhere[15,16]. An aerated 0.05 mol dm^{-3} KSCN solution was used for dosimetry, and the $(SCN)_2^{-\cdot}$ radical was monitored at 500 nm. We calculated the absorbed dose per pulse, assuming G.ε. for the $(SCN)_2^{-\cdot}$ radical to be 23889 dm^3 mol^{-1} cm^{-1} per 100 eV,[17], where G is the radiation chemical yield expressed as the number of molecules formed or destroyed per 100 eV of energy absorbed and ε is the molar absorptivity. The dose employed in the present study, unless otherwise stated, was a typical 16 Gy per pulse.

On irradiation of H_2O, the following primary radicals are produced[18]

$$H_2O \longrightarrow e_{aq}^-, H^\cdot, OH^\cdot \quad (1)$$

For studying the reaction of e_{aq}^- with glycyrrhizic acid, we used an N_2-bubbled aqueous solution containing 0.1 mol dm^{-3} 2-propanol. $OH^\cdot$ and $H^\cdot$ radicals get scavenged by 2-propanol. We measured the rate of reaction of e_{aq}^- with glycyrrhizic acid by monitoring the decay of e_{aq}^- at 700 nm.

To selectively produce $OH^\cdot$ radicals, we saturated solutions with N_2O before pulse irradiation. This resulted in a scavenging of e_{aq}^-, and under these conditions the yield of $OH^\cdot$ radicals is 90% of the total radical yield; $G(OH^\cdot) = 5.4$ mol/100 eV = 5.6×10^{-7} mol J^{-1}. The remaining 10% contribution is of $H^\cdot$ atoms $G(H^\cdot) = 0.6$ mol/100 eV = 0.62×10^{-7} mol J^{-1}.

$$e_{aq}^- + N_2O \xrightarrow{H_2O} OH^\cdot + OH^- + N_2 \quad (2)$$

We measured the rate of reaction of $OH^\cdot$ radicals with glycyrrhizic acid by monitoring the buildup kinetics at 320 nm.

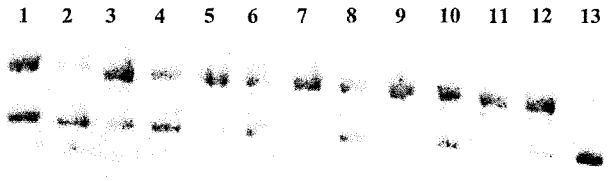

Fig. 2. Agarose gel electrophoresis pattern of pBR322 DNA exposed to various doses of γ-radiation in the presence and absence of 2.5 mM GZA (negative of the photograph). The upper and lower bands depict the open circular (oc) and the supercoiled (ccc) forms, respectively. Lanes 1, 3, 5, 7, 9, and 11 depict the results of pBR322 degradation to oc form at the radiation doses of 10, 20, 30, 40, 50, and 100 Gy, respectively, without the presence of the compound. Lanes 2, 4, 6, 8, 10, and 11 show the effect of the presence of GZA at the same radiation doses, respectively. Lane 13 is the control lane (without radiation).

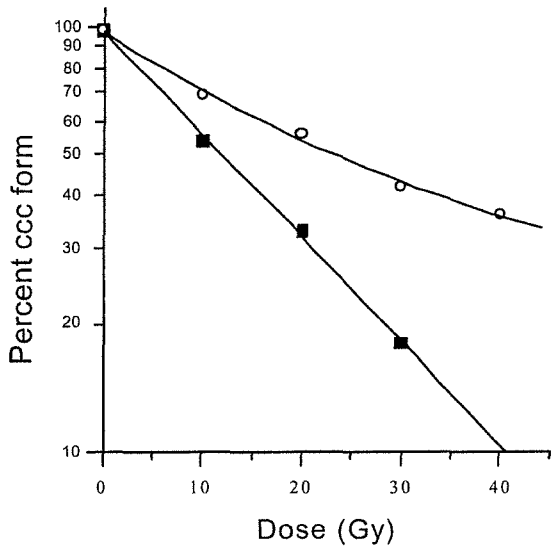

Fig. 3. Presents the quantified data from Fig. 1 analyzed by Syngene Software (Syngene Inc., USA). Each point is the average of the three independent experiments. The dose-reduction factor for glycyrrhizic acid (2.5 mM) for the protection of the DNA in vitro was determined to be 2.04.

The rates of reactions were determined by carrying out the experiments with at least three different concentrations of glycyrrhizic acid, varying by at least a factor of 4. Bimolecular rate constants were derived from plots of the first-order rates vs. concentration. The calculated bimolecular rates are within the limits of ± 15% experimental error.

Statistical analysis

The results are represented as mean ± standard error of mean (mean ± SEM). ANOVA was done by using origin 5.0. The results are significant at $p<0.01$ and $p<0.05$

RESULTS

The reverse of a photo negative of the agarose gel electrophoresis of pBR322 DNA exposed to various doses of γ-radiation in the presence and absence of 2.5 mM GZA is given in Fig. 2. As compared to control, the exposure of plasmid DNA to gamma radiation decreased the relative intensity of the ccc form of DNA. This decrease was dependent on the increase in the radiation dose, as could be seen in lanes 1, 3, 5, 7, 9, and 11. The presence of GZA along with DNA during irradiation prevented this decrease of the ccc form, as evident in lanes 2, 4, 6, 8, 10, and 12. This would suggest that GZA offered protection to DNA in vitro against gamma radiation induced strand breaks. The reduction in the quantity of the supercoiled (ccc) form of plasmid DNA is directly related to the radiation-induced damage, particularly strand breaks in DNA. There was a dose-dependent reduction of the ccc form of plasmid DNA when exposed to 0-100 Gy of gamma radiation, and the presence of 2.5mM GZA prevented this loss of ccc form, as can be seen in Fig. 3. The dose-reduction factor (DRF) for the DNA at 2.5mM GZA calculated from the data is 2.04.

An exposure to γ-radiation ex vivo induces damage to the DNA of human peripheral blood leukocytes, as can be

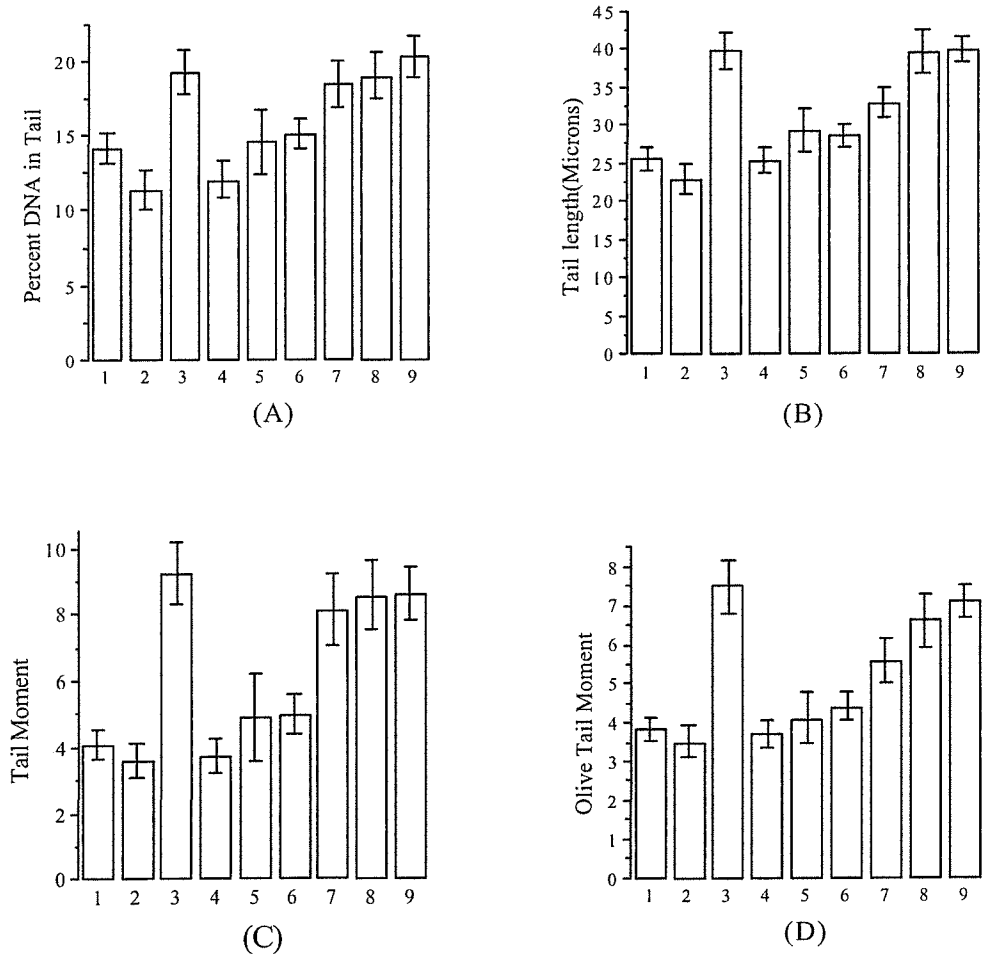

Fig. 4. Effect of Various concentrations on γ-radiation-induced DNA damage in human blood lymphocytes, estimated by comet assay in terms of the percent DNA in tail (A), tail length (B), tail moment (C), and Olive tail moment (D). 1: control; 2: GZA (1.0 mM) alone; 3: 2 Gy radiation alone; 4, 5, 6, 7, 8, and 9: 2 Gy radiation + 10, 7.5, 5, 2.5, 1.0, and 0.5 mM GZA, respectively.

inferred from the data on comet assay presented in Fig. 4. An exposure of human peripheral blood leucocytes to 2 Gy γ-radiation ex vivo resulted in increases of the comet parameters, such as % DNA in tail, tail length, tail moment, and Olive tail moment, and the presence of GZA during irradiation inhibited these increases in a concentration-dependent manner (Fig. 4, a–d). These results thus suggest a protection of cellular DNA by GZA from radiation damage.

Figures 5 and 6 depict the results of comet assay performed on blood leukocytes and bone marrow cells from whole-body irradiated mice treated with GZA. The whole-body exposure of animals to gamma radiation (4Gy) resulted in an increase in the comet parameters (such as % DNA in tail, tail length, tail moment, and Olive tail moment) of the cells of blood leucocytes and bone marrow as a result of damage to cellular DNA. When GZA was administered 1 hr befofre irradiation, there was a significant decrease in comet parameters in blood leucocytes and bone marrow cells of irradiated mice (Figs. 5 and 6). When the animals were exposed to gamma radiation (4 Gy), % DNA in the tail was increased from 3.117 ± 0.45 to 8.133 ± 0.54, tail length was increased from 8.631 ± 0.94 to 26.158 ± 1.49, tail moment was increased from 0.689 ± 0.21 to 3.475 ± 0.44, and Olive tail moment was increased from 0.869 ± 0.15 to 3.626 ± 0.32 in blood cells. But the administration of GZA 1 hour before irradiation brought these parameters down to levels of 6.496 ± 0.54, 22.016 ± 1.39, 2.728 ± 0.41, and 2.555 ± 0.25, respectively, in the irradiated animals (Fig. 5, A–D).

In the bone marrow cells of animals exposed to radiation (4 Gy), % DNA in tail, tail length, tail moment, and Olive

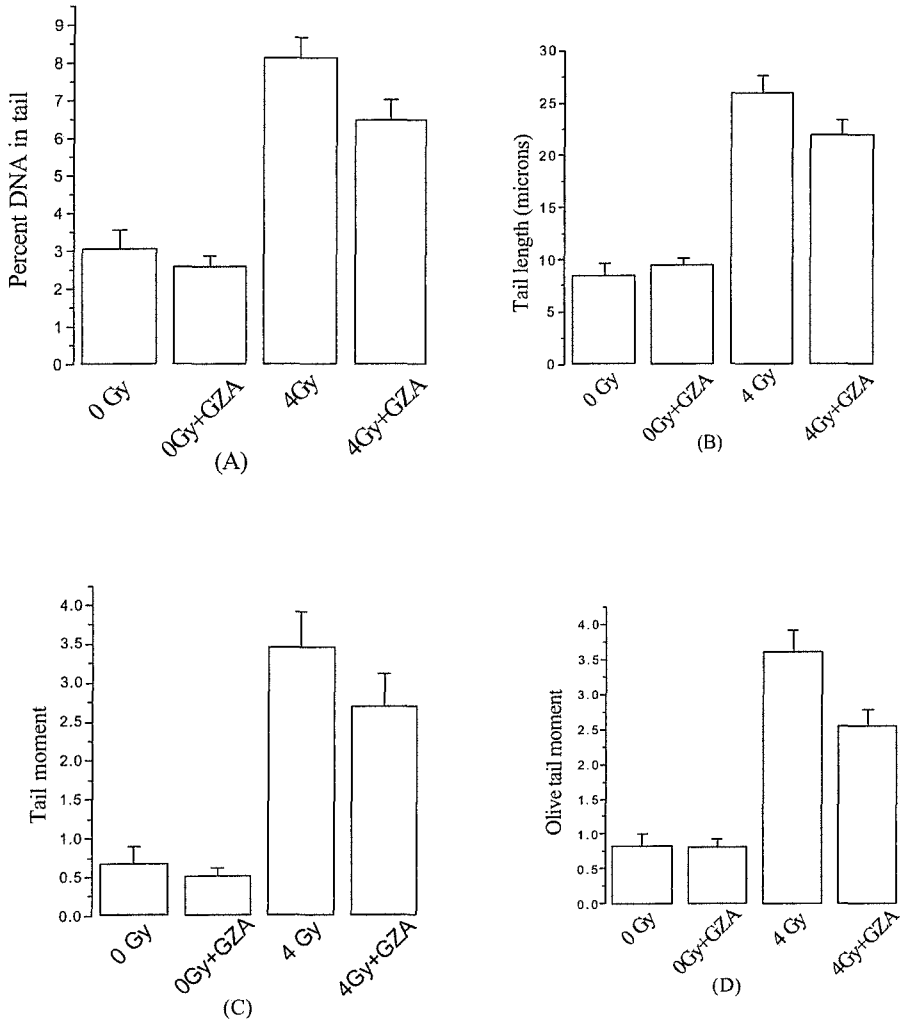

Fig. 5. Effect of Glycyrrhizic acid on DNA damage in murine blood leucocytes assayed by Comet assay: (a) % DNA in tail; (b) Tail length; (c) Tail moment; (d) Olive tail moment. (Why small letters here (a), (b), etc., and capital letters in Figs. 4 and 6 (A), (B), etc.?) (And why capitalize Tail length and Tail moment here and below when you didn't above in Fig. 5? Please be consistent.)

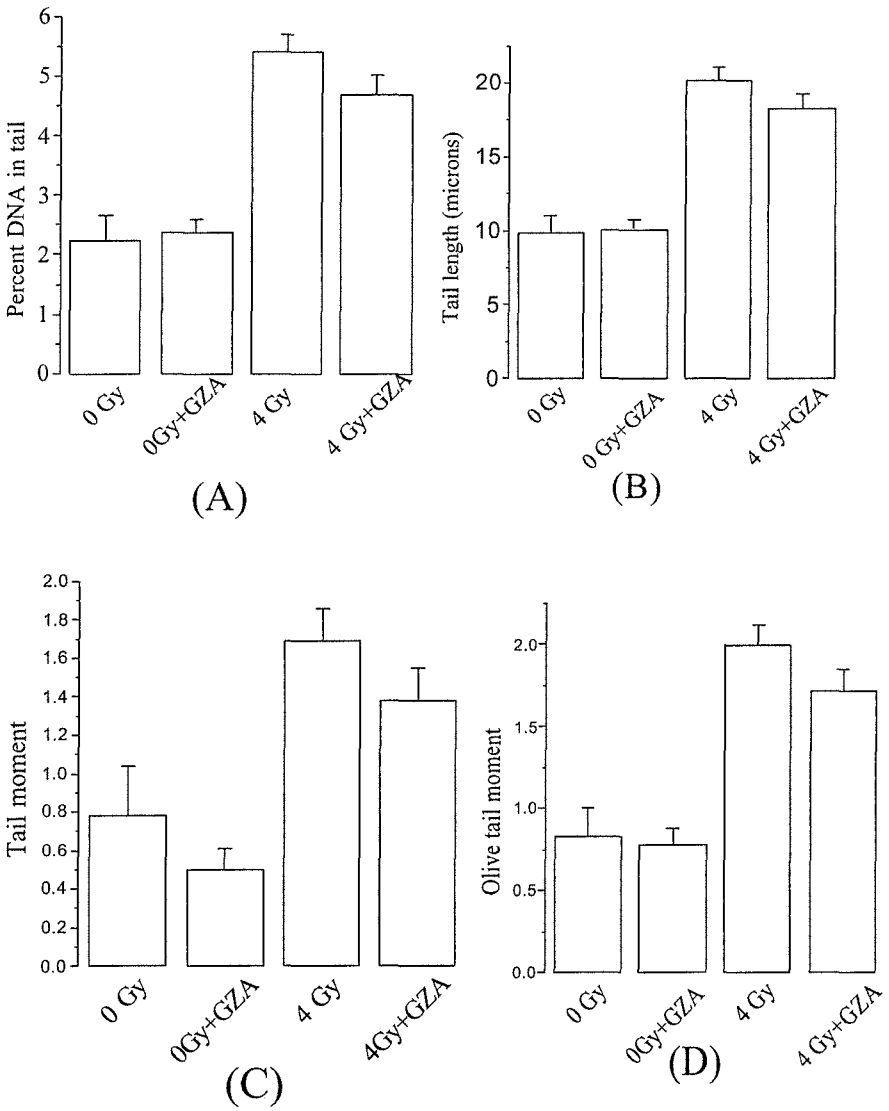

Fig. 6. Effect of Glycyrrhizic acid on DNA damage in murine bone marrow cells assayed by Comet assay, (A) % DNA in tail (B) Tail length (C) Tail moment and (D) Olive tail moment.

tail moment was increased from the respective control value 2.265 ± 0.4, 9.971 ± 1.12, 0.787 ± 0.27, and 0.832 ± 0.18 to 5.412 ± 0.29, 20.19 ± 0.95, 1.704 ± 0.16, and 2.001 ± 0.12. The administration of GZA 1 hour before irradiation brought these levels down to 4.702 ± 0.32, 18.376 ± 0.088, 1.392 ± 0.16, and 1.73 ± 0.13, respectively, in the irradiated animals (Fig. 6, A–D).

The mechanism of radioprotection by GZA was investigated by pulse radiolysis studies. The transient absorption spectra obtained on the reaction of glycyrrhizic acid with OH radicals is presented in Fig. 7. The bimolecular rate constants for the reactions of $OH^{\cdot}$ and e_{aq}^{-} with GZA were determined as explained in materials and methods and found to be 1.2×10^{10} M^{-1} s^{-1} and 3.9×10^{9} M^{-1} s^{-1}, respectively. The transient produced on reaction with OH radical shows an absorption maximum at 320 nm and did not decay up to 2 milliseconds, both in the presence and absence of air. However, we could observe no transient formation on the reaction of GZA with e_{aq}^{-} in the wavelength region of 280 nm to 700 nm under our experimental conditions.

To see the radioprotection of GZA, pulse radiolysis experiments were carried out. Experimental conditions were chosen in such a way that the electron and the OH radicals reacted selectively with Thymine in the presence of GZA. It was observed that e_{aq}^{-} and $OH^{\cdot}$ radical adducts of thymine were found to be nonreactive toward glycyrrhizic acid (our unpublished observations). The results thus indicate that glycyrrhizic acid offers radioprotection by a scavenging of free radicals.

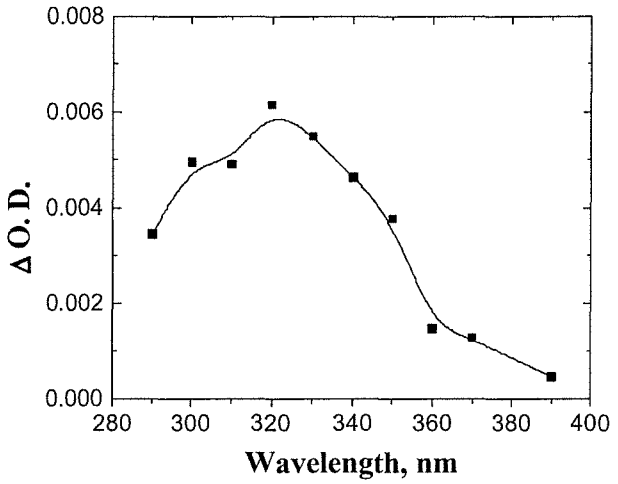

Fig. 7. Transient absorption spectrum obtained on pulse irradiation of N_2O saturated solution containing 1×10^{-4} mol dm^{-3} Glycyrrhizic acid at pH 7. Dose = 16 Gy.

DISCUSSION

DNA constitutes the primary vital target for cellular inactivation of living systems by ionizing radiation. The present study shows that DNA is protected from the deleterious effects of γ-radiation by GZA in the in vitro, ex vivo, and in vivo conditions of radiation exposure. Ionizing radiation-induced damages to cellular DNA are mainly strand breaks of the double- and single-strand types, base damages, elimination of bases, and sugar damage[19]. In the in vitro studies, it was found that when the plasmid pBR322 was exposed to γ-radiation, the ccc form of the molecule was converted to the oc form, with a difference in the mobility in the agarose gel because of the induction of strand breaks in the DNA. Several phytochemicals have been shown to be radioprotectors[20–24].

Nontoxic compounds that can protect DNA against ionzing radiation have considerable potential as radioprotectors and could be of use in preventing diseases like cancer and degenerative diseases arising from gene mutations. GZA does not induce DNA damage by itself, but it inhibits the induction of single- strand breaks in DNA by γ-radiation. The ability of GZA to protect DNA in vitro is determined, as a dose-reduction factor (DRF), from the dose response curve for undamaged ccc DNA remain after exposure to various doses of radiation. The DRF for the plasmid DNA at 2.5 mM GZA is 2.04.

The damages by ionizing radiation to DNA can cause the loss of viability of the cells exposed to radiation. The alkaline comet assay is an elegant and effective technique to monitor the extent of the DNA damage and its protection. When the human leucocytes are exposed to γ-radiation ex vivo, the cellular DNA undergoes damage, as reflected in the increase of the comet parameters (tail length, tail moment, % DNA in the tail, among others). GZA's presence during irradiation of the cells decreases the comet parameters in a concentration-dependent manner indicative of radiation protection.

Whole-body exposure of animals to gamma radiation (4 Gy) resulted in an increase in the comet parameters of cells of various tissues and tumors because of damage to cellular DNA[8,12,13]. The IP administration of GZA to mice before whole-body irradiation protected the mice because there was a decrease in the comet parameters in various tissues, such as bone marrow and blood cells. The results presented in our work clearly show that the GZA protects bone marrow cells from the radiation-induced damages. This would suggest that GZA could be a potential drug for the protection of the hemopoietic system from radiation-induced lesions.

To understand the mechanism of radioprotection by GZA at a molecular level, we have studied by pulse radiolysis technique the transient absorption spectra of glycyrrhizic acid on reaction with OH radicals. Glycyrrhizic acid reacted with $OH^{\cdot}$ and e_{aq}^{-} with rate constants 1.2×10^{10} M^{-1} s^{-1} and 3.9×10^{9} M^{-1} s^{-1}, respectively. The results thus indicate that glycyrrhizic acid offers radioprotection by the scavenging of free radicals.

GZA is the main active ingredient of liquorice, a natural sweet substance originating from the root of the genus *Glycyrrhizia*. This genus contains about 14 species with varying degrees of sweetness, such as *glabra* (Spanish), *glandulifera* (Russian and Persian), *echinata* (German), *uralensis* (Asian), and *lepidota* (American). Among them, the main source of medicinal liquorice is *Glycyrrhizia glabra*. Liquorice has been used since ancient times as an herbal remedy for coughs, peptic ulcers, constipation, stomachache, arthritis, insomnia, depression, fatigue, asthma, and liver problems. It is administered in such forms as liquid extract, powder, concentrate, infusion, tablet, capsules, tincture, candy, gum, tea, soft drinks, and alcoholic drinks. The undesirable side effects of liquorice include water and sodium retention, hypertension, hypokalemia, and alkalosis, and these are reversible if it is discontinued. Liquorice contains 0.2% GZA. An acceptable daily intake of GZA for human subjects was estimated to be 0.2 mg/kg body weight.[25]. Our findings reveal that GZA protects cellular DNA against radiation-induced damage. One deleterious consequence of DNA damage from exposure to ionizing radiation is the induction of cancer. Protecting cellular DNA from radiation damage might result in the prevention of the cancers induced by the radiation. Recently it has been reported that diagnostic X-rays -though they provide great benefits -do cause a risk of cancer[26]. GZA or liquorice administration to the patients undergoing medical X-ray exposures might reduce the incidence of these cancers.

Summary

Background: We have previously shown that natural honey is able to protect the rat stomach against acute ethanol- and indomethacin-induced lesions. The present investigations were undertaken to examine the role of intraluminal osmolality in this protective effect. **Methods:** Mannitol, glucose-fructose-sucrose-maltose mixture (GFSM) and natural honey (300, 600, 1800 mOsmol/kg water) were given orally to rats 30 min before administration of 70% ethanol for a further 15-min period. Lesions area of the excised stomachs were evaluated. Pylorus-ligated stomachs were filled with mannitol, GFSM mixture and honey (1800 mOsmol/kg water) to test the effect of the hyperosmolar solutions on gastric fluid content and acid secretion. The rate of gastric emptying of the three test solutions (1800 mOsmol/kg) was measured by the phenol red method. **Results:** Intragastric administration of mannitol, GFSM mixture or honey prevented the formation of mucosal lesions in an osmolality-dependent manner. Using the pylorus-ligated stomach model, the test solutions led to a net increase of luminal fluid volume without affecting acid content. Hyperosmolar solutions presented a delayed gastric emptying if compared to a nonnutrient solution made of carboxymethyl cellulose. **Conclusions:** The observed results suggest that hyperosmolar solutions can prevent the formation of hemorrhagic lesions by luminal dilution of the necrotising agent and acid, an effect which may be potentiated by a lowered gastric emptying rate.

Honey is elaborated by honey bees from sugars present in the nectar of various plants. Besides carbohydrates which are the major constituents (70–80%), honey contains, in low amounts, various substances such as organic acids, proteins, amino acids, vitamins, enzymes, minerals and different other molecules (pigments, flavonoids, antibacterial factors, etc.) (1). Since ancient times, people know the curative properties of honey. The ancient Greeks, Romans, Chinese and Egyptians used honey to heal wounds and to cure gut diseases (2). Several reports have shown the effectiveness of natural honey in the treatment of wound ulcers and skin burns (3–8). Furthermore, it has been recently shown that the growth of *Helicobacter pylori*, a causative agent in duodenal ulcer, can be prevented by manuka honey (9). Few reports have shown the effectiveness of honey in gastric ulcers and gastroenteritis (10, 11). It has been reported that natural honey is able to protect rat stomach against acute ethanol- and indomethacin-induced lesions and to accelerate the healing of rat antral ulcers induced by indomethacin (12–14). Ali et al. have pointed out that protection of the stomach against necrotising agents by honey is dose- and time-dependent (15). Enhancement of gastric fluid volume subsequent to intragastric instillation of hyperosmolar solutions may be an important mechanism by which honey or a combination of sugars provide mucosal protection. The present study was undertaken to examine the role of luminal osmolality in the protective effect of honey against ethanol-induced

gastric lesions in rats. Gastric protection induced by honey was compared with that of mannitol and a glucose-fructose-sucrose-maltose (GFSM) mixture formulated to match the content of sugars in honeys. In a second experiment, hyperosmolar and efficiently protective solutions were used to test their effect on water and acid secretion by the pylorus-ligated stomach and to measure their gastric emptying rate.

Material and methods

Animal treatment: Male Wistar rats weighing between 200–250 g were deprived of food for 48 h, but they were allowed free access to tap water until 1 h before the experiment. During the fasting period, the animals were placed individually in cages with wide-mesh wire bottoms to prevent coprophagy.

Ethanol-induced gastric lesions: Treated animals received 5 ml/kg of 300 mOsmol/kg water NaCl (controls) or the same dose of test solution by orogastric intubation. Thirty minutes after their pretreatment, the animals were gavaged with 70% ethanol (5 ml/kg). They were killed 15 min later by cervical dislocation and their stomach rapidly removed after ligating both oesophageal and pyloric ends. Each stomach was opened along the greater curvature, its content was drained and completely recovered by washing with 10 ml isotonic saline. The recovered solution was weighed and centrifuged (3500 rpm for 10 min) to remove contaminating debris. Samples with more than 0.3 ml of sediment were discarded. Supernatants were used for acid determination.

Each stomach was pinned flat on a corkboard and fixed with 10% formalin (10–15 min). Using a colour CCD-camera (DIC-D, World Precision Instr., Sarasota, Florida), the stomach images were coded and stored in a personal computer for subsequent lesions analysis by an observer unaware of the treatments (S. K.). Lesions analysis was performed using the UTHSCA ImageTool program (developed at the University of Texas Health Science Center at San Antonio, Texas, and available from the Internet by anonymous FTP from maxrad6.uthsca.edu). Lesions were delimited manually and the resulting pixels area converted in mm^2 by the ImageTool program using an internal conversion factor. The total area of lesions was determined for each stomach and the treatment mean of the group used for comparison.

Gastric secretion: In order to test the effect of the gastroprotective test solutions on water and acid secretion, the pylorus ligated stomach model was used. Laparotomy and pylorus ligation were performed under light ether anaesthesia. Just after ligation of the pylorus, animals received 5 ml/kg of mannitol, GFSM mixture or honey solution (1800 mOsmol/kg water). Animals regain righting reflex 5–15 min after operation. Conscious animals were killed 4 h after pylorus ligation by cervical dislocation. The stomachs were removed immediately and processed as previously described for fluid recovery.

Water and acid determinations: Aliquots of the test solutions were used to measure free acidity. Free acidity (mEq/l) was determined by titration of the sample to pH 7 using 0.1 N NaOH and an automatic titrator (Orion EA960 Titrator, Boston, USA). Concentration and free acidity of the test solutions are shown in table 1.

Table 1. Composition and total acidity of the test solutions.

Test solution (mOsmol/kg water)	Composition (g/100 g water)	Total acidity (mEq/l)
Mannitol		
300	5.088	0.15
600	9.460	0.15
1800	23.072	0.15
GFSM mixture		
300	6.262	0.88
600	12.768	0.88
1800	35.758	0.88
Honey		
300	6.264	2.43
600	12.040	4.05
1800	29.400	7.90

Stomach fluid content was calculated by subtracting the volume of the washing solution from that of the recovered solution. Acid content was determined in the same manner as in the test solutions. Water and acid contents were expressed in ml and µEq per 200 g body weight, respectively.

Measurement of gastric emptying: Gastric emptying was measured according to the method described by Barquist et al. (1992) (16). A solution containing honey, GFSM mixture or mannitol (1800 mOsmol/kg water) and phenol red (50 mg/100 ml) was given intragastrically (1.5 ml) through a stainless steel tube in conscious rats. After a period of 20 min, animals were killed by cervical dislocation. Control animals received a nonnutrient solution containing 1.5% carboxymethyl cellulose and phenol red. Animals serving as standards (reference stomach, 0% emptying rate) were killed immediately after the intubation. Stomachs were ligated at the pylorus and cardia, removed and homogenized in 100 ml 0.1 N NaOH. After allowing the suspension so settle at room temperature for 60 min, 5 ml of the supernatant was added to 0.5 ml of 20% TCA and centrifuged (3000 rpm for 30 min at 4 °C). The supernatant was mixed with 4 ml 0.5 N NaOH and the absorbance was read at 560 nm. Gastric emptying was calculated according to the following formula:

$$\frac{(A_{560}\ \text{ref} - A_{560}\ \text{sample}) \times 100}{A_{560}\ \text{ref}}$$

Substances and test solutions: An unprocessed specimen of natural honey were gathered directly from a local bee-keeper. GFSM mixture was prepared by mixing the sugars together in the same proportions as they are found in honeys (17). To 17.5 ml of distilled water were added 38.2 g fructose, 31.3 g glucose, 1.5 g sucrose and 7.3 g maltose. The solution was heated briefly to 50 °C to accelerate the dissolving of sugars.

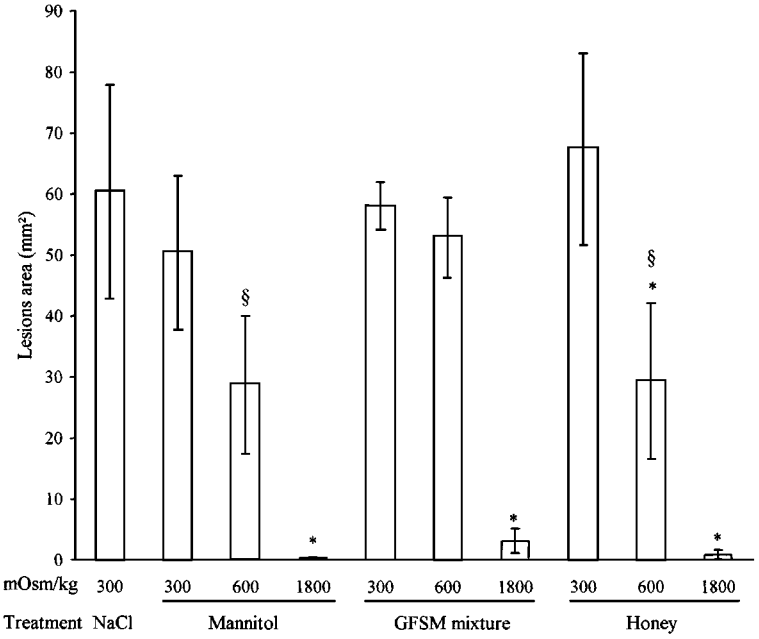

Fig. 1. Effect of intragastric instillation of mannitol, GFSM mixture and honey on ethanol-induced gastric lesions. Test solutions were administered 30 min prior to 70% ethanol instillation. Values are means ± SE (n = 9–10). *: comparisons with respect to control (NaCl), $P < 0.05$; §: comparisons with respect to 600 mOsmol/kg GFSM mixture, $P < 0.05$.

Table 2. Effect of intragastric instillation of mannitol, GFSM mixture and honey and subsequent treatment with ethanol on luminal fluid content.

Treatment	Luminal fluid volume (ml/200 g)	Acid content (µEq/200 g)	Acid concentration (µEq/ml)
Control	1.21 ± 0.11	14.11 ± 4.23	12.42 ± 3.86
Mannitol (mOsmol/kg water)			
300	1.27 ± 0.19	3.94 ± 1.49*	3.15 ± 1.69*
600	1.50 ± 0.20	13.25 ± 4.09	6.34 ± 1.53*
1800	1.64 ± 0.16	16.63 ± 2.67	9.97± 1.29
GFSM mixture (mOsmol/kg water)			
300	1.31 ± 0.17	1.90 ± 3.21*	0.10 ± 3.04*
600	1.52 ± 0.10	9.30 ± 2.72*	6.64 ± 2.07*
1800	1.57 ± 0.12	11.68 ± 2.26	7.33 ± 3.56*
Honey (mOsmol/kg water)			
300	1.61 ± 0.14	1.04 ± 2.32*	1.31 ± 1.52*
600	1.25 ± 0.17	11.97 ± 1.57	9.72 ± 1.39*
1800	1.28 ± 0.10	14.22 ± 2.78	11.29 ± 2.27

Test solutions were administered 30 min prior to 70% ethanol instillation. Values are means ± SE (n = 9–10). Comparisons are made with respect to control (isotonic NaCl). * $P < 0.05$.

The test solutions of mannitol, GFSM mixture and honey were prepared by dissolving the appropriate amount of matter in distilled water to obtain an osmolality equivalent to 300, 600 and 1800 mOsmol/kg water. Osmolality was determined using a cryoscopic osmometer (Osmomat 030, Gonotech, Germany) calibrated with NaCl solution (2500 mOsmol/kg water). All chemicals were of analytical grade.

Statistical analysis: Data are expressed as means ± SE. Statistical analyses were performed using analysis of variance followed by Dunnett's test for multiple comparisons with respect to control and Student test for comparisons between treatment groups. Values of $P < 0.05$ were regarded as indicating significant differences.

Results

Gastric damage: Gastric instillation of 70% ethanol resulted in mucosal damage. The area covered by hemorrhagic lesions was 60.5 ± 22.6 mm^2. Pretreatment of animals with 300 mOsmol/kg water mannitol, GFSM mixture or honey solutions was without effect on mucosal lesions area (mean area: 58.7 mm^2). Increasing luminal osmolality from 300 to 600 and 1800 mOsmol/kg led to a significant reduction of the lesions ($P < 0.05$), except for 600 mOsmol/kg GFSM mixture which induced only 12.4% protection. The protection of the stomach was almost total when using the highest osmolality (fig. 1).

Water and acid content of ethanol-treated stomachs: Fluid content of the stomach did not vary significantly when animals were given mannitol, GFSM mixture or honey solutions prior to ethanol intubation (table 2). Oral administration of each test solution showed an increase of acid content with increasing osmolality of the solution. If compared to controls, acid content was significantly reduced when using 300 mOsmol/kg mannitol, GFSM mixture or honey ($P < 0.05$; table 2).

Water and acid secretion by pylorus-ligated stomach: In control animals (stomach filled with

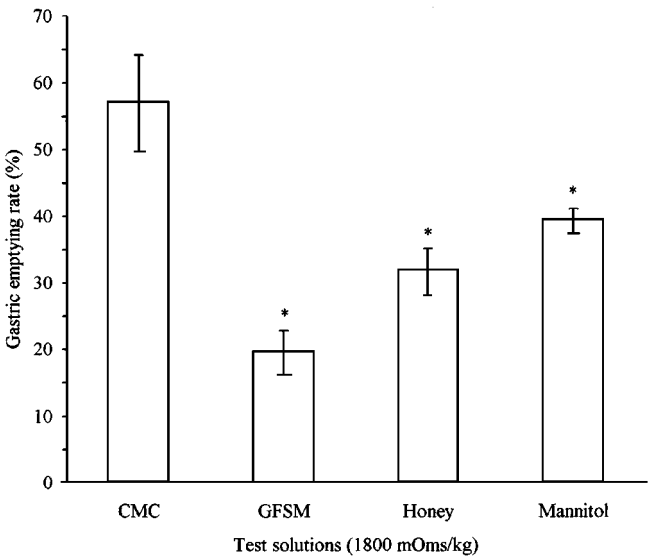
Table 3. Effects of mannitol, GFSM mixture and honey (1800 mOsmol/kg water) on fluid and acid secretion by the pylorus ligated stomach.

Treatment	Luminal fluid volume (ml/200 g)	Acid content (µEq/200 g)	Acid concentration (µEq/ml)
Control	2.91 ± 0.44	282.4 ± 40.8	91.2 ± 20.4
Test solutions (1800 mOsmol/kg water)			
Mannitol	4.57 ± 0.40*	329.2 ± 61.6	62.5 ± 8.9*
GFSM mixture	4.68 ± 0.20*	276.2 ± 67.4	43.6 ± 7.6*
Honey	5.18 ± 0.40*	340.8 ± 56.1	57.2 ± 5.9*

The stomachs were filled with test solution for 4 h. Values are means ± SE (n = 7–8). Comparisons are made with respect to control (isotonic NaCl). * $P < 0.05$

300 mOsmol/kg water NaCl), the volume of luminal fluid reached 2.91 ± 0.44 ml/200 g 4 h after ligation of the pylorus. When the stomach was filled with 1800 mOsmol/kg mannitol, GFSM mixture or honey solution, fluid content was increased by 57%, 61% and 78%, respectively (table 3). Parallel to a significant decrease of acid concentration in the lumen, ranging from 30.5 to 53.7%, acid content was not significantly changed (table 3).

Gastric emptying: A CMC solution (1.5%) was used as a control solution for two main reasons: (1) it possesses a viscosity similar to the test solutions and is considered as non-nutritive, (2) it is devoid of molecules which can directly interfere with osmoreceptors. In animals given the nonnutrient solution, the rate of gastric emptying was 57.1 ± 7.1%. Honey, GFSM mixture and mannitol solutions (1800 mOsmol/kg) presented a significantly lower rate than that of CMC solution ($P < 0.05$; fig. 2). The observed rates were varying according to the nature of the test solution (mannitol > honey > GFSM mixture).



Discussion

The present results show that gastric instillation of isotonic mannitol, GFSM mixture or honey did not prevent mucosal lesions formation induced by 70% ethanol. Whereas animal pretreatment with hyperosmolar solutions (1800 mOsmol/kg) reduced lesions area to almost zero. The effects of 600 mOsmol/kg solutions was variable according to the nature of the solution used. Both 600 mOsmol mannitol and honey solutions led to approximately 52% protection whereas GFSM mixture had no effect at the same osmolality. Parallel to an increase of the percent protection, acid content of the stomach tended to increase with increasing the osmolality of the test solution. These results are in agreement with those reported earlier (12–15, 18). Furthermore, it has been shown that hyperosmolar solutions of mannitol (5–30%) present a concentration-dependent protective effect against absolute ethanol-induced mucosal damage in rats (19). The absence of protective effect of 600 mOsmol/kg GFSM mixture solution suggests that both sugars and non sugar components of natural honey are involved in gastroprotection. At higher osmolality, the role of carbohydrates becomes indiscernible from that of non sugar components. It has been reported that honey can induce a partial protection if given at a dose of 5 g/kg body weight (1 g mixed with 1 ml 100% ethanol) and that a GFSM mixture at the same dose had no effect (12). Gastric protection by mannitol may be attributed to both its osmotic and antioxidant properties.

Gastric administration of the test solutions prior to ethanol led to an increase of acidity in the stomach parallel to a reduction of lesions area; this change was not correlated to initial acidity of the test solution. It has long been recognised that gastric damage is followed by a disappearance of acid from the gastric lumen and an increase of gastric blood flow (20, 21). Acid disappearance has been attributed to back-diffusion of acid through the disrupted gastric barrier (22) and neutralisation of the influxing acid by an increased efflux of bicarbonate (23).

Mannitol, GFSM mixture and honey (1800 mOsmol/kg) led to a significant increase of fluid in the ligated stomach. The net decrease of acid concentration in the gastric lumen is due to the increase of fluid volume without parallel change in acid content. These results suggest that these test solutions act on fluid secretion by an osmotic effect. A slight increase of fluid was also observed in ethanol-induced lesions model but without reaching a statistically significant level. Experiments undertaken to measure gastric emptying showed that

Fig. 2. Gastric emptying rate of hyperosmolar solutions of mannitol, GFSM mixture and honey. Measurements were made 20 min after intragastric administration of the test solutions. Values are means ± SE (n = 7–8). Comparisons are made with respect to control (CMC, 1.5% carboxymethyl cellulose). * $P < 0.05$.

hyperosmolar solutions of mannitol, GFSM mixture and honey present a lower rate of gastric emptying. Acutely induced hyperglycaemia in man and hyperosmolar glucose solution were shown to slow the rate of gastric emptying (24–26). In pylorus-ligated stomach model, both luminal hypertonicity and stimulation of fluid secretion may be involved in the rise of fluid volume. The slowing of gastric emptying by hyperosmolar solutions has been postulated to result from the triggering of duodenal osmoreceptor feedback on the stomach (26, 27). The delay of gastric emptying induced by hyperosmolar mannitol, GFSM mixture or honey solution may lead to a dilution of ethanol given 30 min later. Under these conditions, the luminal concentration of ethanol, given as a necrotising agent, would be insufficient to provoke mucosal damage. Ethanol is a potent gastric barrier disrupting agent if administered at a concentration greater than 50% (28). Despite the fact that hyperosmolar solutions can slow gastric emptying and induce fluid secretion, an increased fluid volume in the ethanol-induced lesions model was not observed. This may be due to an insufficient time that allows accumulation of secreted fluid in the lumen, and to the contractions of the stomach that follow ethanol administration (29). It has been shown that some mild irritants (HCl, NaCl) can induce volume increase that by itself is enough to afford protection through luminal dilution (28).

In conclusion, it appears that mannitol, GFSM mixture and natural honey solutions prevented gastric lesions in an osmolality-dependent manner. Total protection of the stomach against 70% ethanol can be obtained with hyperosmolar sugars solutions (osmolality greater than 600 mOsmol/kg water). The gastroprotective effect of these substances may be attributed to luminal osmolality and delayed gastric emptying which act to lower the concentration of the necrotizing agent and secreted acid.

CONTENTS

FOREWORD

I am pleased to present the World Health Organization's Global status report on alcohol and health 2014. WHO has published several reports in the past on this topic with the last one being published in 2011, but this report of 2014 has some unique features. First, it describes some progress made in alcohol policy development in WHO Member States after endorsement of the Global strategy to reduce the harmful use of alcohol in 2010. Second, this report provides a wealth of information on alcohol-related indicators for the comprehensive global monitoring framework for the prevention and control of non-communicable diseases (NCDs) adopted by the 66th World Health Assembly. The global monitoring framework was developed to fulfil the mandate given by the Political Declaration of the High-level Meeting of the General Assembly on the Prevention and Control of Non-communicable Diseases (NCDs) and includes the voluntary target of a 10% relative reduction in harmful use of alcohol by 2025 measured against a 2010 baseline. Thirdly, this report presents an overview of some of the mechanisms and pathways which underlie the impact of the harmful use of alcohol on public health.

The report highlights some progress achieved in WHO Member States in the development and implementation of alcohol policies according to the ten areas of action at the national level recommended by the Global strategy. This progress is uneven and there is no room for complacency given the enormous public health burden attributable to alcohol consumption. Globally, harmful use of alcohol causes approximately 3.3 million deaths every year (or 5.9% of all deaths), and 5.1% of the global burden of disease is attributable to alcohol consumption. We now have an extended knowledge of the causal relationship between alcohol consumption and more than 200 health conditions, including the new data on causal relationships between the harmful use of alcohol and the incidence and clinical outcomes of infectious diseases such as tuberculosis, HIV/AIDS and pneumonia. Considering that beyond health consequences, the harmful use of alcohol inflicts significant social and economic losses on individuals and society at large, the harmful use of alcohol continues to be a factor that has to be addressed to ensure sustained social and economic development throughout the world. In the light of a growing population worldwide and the predicted increase in alcohol consumption in the world, the alcohol-attributable disease burden as well as the social and economic burden may increase further unless effective prevention policies and measures based on the best available evidence are implemented worldwide. And, importantly, we know that in countries with lower economic wealth the morbidity and mortality risks are higher per litre of pure alcohol consumed than in the higher income countries.

Following the endorsement of the Global strategy to reduce the harmful use of alcohol WHO has strengthened its actions and activities to prevent and reduce alcohol-related harm at all levels. Several regions have developed and adopted regional strategies focusing on the target areas recommended in the global strategy. At the global level the WHO Secretariat has facilitated establishment of a global network of WHO national counterparts as well as a coordinating council to ensure effective collaboration with and between Member States. At the same time all the efforts and resources available at all levels are clearly not adequate to confront the enormous public health burden caused by the harmful use of alcohol, and further progress is needed at all levels and by all relevant actors to

achieve the objectives of the Global alcohol strategy and the voluntary global target of at least a 10% relative reduction in the harmful use of alcohol by 2025. WHO is prepared and committed to continue to monitor, report and disseminate the best available knowledge on alcohol consumption, alcohol-related harm and policy responses at all levels, which is key to monitoring progress in implementing the Global strategy and regional action plans. Accurate and up-to-date information is vital for alcohol policy development, and I hope that you will find this report, which is largely based on the information submitted from Member States, useful in contributing to the public health objectives articulated in the Global strategy to reduce the harmful use of alcohol.

Oleg Chestnov
Assistant Director-General
Noncommunicable Diseases and Mental Health

ACKNOWLEDGEMENTS

The report was produced by the Management of Substance Abuse Unit (MSB) in the Department of Mental Health and Substance Abuse (MSD) of the World Health Organization (WHO), Geneva, Switzerland. The report was developed within the framework of WHO activities on global monitoring of alcohol consumption, alcohol-related harm and policy responses, and is linked to WHO's work on the Global Information System on Alcohol and Health (GISAH).

Executive editors: Vladimir Poznyak and Dag Rekve.

Within the WHO Secretariat, Oleg Chestnov, Assistant Director-General, Noncommunicable Diseases and Mental Health, and Shekhar Saxena, Director, Department of Mental Health and Substance Abuse, provided vision, guidance, support and valuable contributions to this project.

The WHO staff involved in development and production of this report are: Alexandra Fleischmann, Vladimir Poznyak, Dag Rekve and Maria Renström of the WHO MSD/MSB unit at WHO Headquarters in Geneva. The report benefited from technical inputs from Nicolas Clark of WHO MSD/MSB. Linda Laatikainen provided a significant contribution to the production of the report during its final stages in her capacity as a consultant. Gretchen Stevens and Colin Mathers from the Department of Health Statistics and Information Systems, contributed to the estimates of alcohol-attributable disease burden and provided technical input at all stages of the report's development. Margie Peden from the Department of Violence and Injury Prevention provided technical input to the report at different stages of its development. Leanne Riley, Regina Guthold and Melanie Cowan from the Department of Prevention of Noncommunicable Diseases provided data from the WHO-supported surveys and technical input to the report. Florence Rusciano from the Department of Health Statistics and Information Systems created the maps used in the report.

Preparation of this report is a collaborative effort of the WHO Department of Mental Health and Substance Abuse, Management of Substance Abuse, with the Centre for Addiction and Mental Health (CAMH), Toronto, Canada. The contributions from Jürgen Rehm, Kevin Shield, Margaret Rylett (CAMH, Canada) as well as from Gerhard Gmel and Florian Labhart (Addiction Info, Switzerland) and David Jernigan and Marissa Esser (Johns Hopkins Bloomberg School of Public Health, USA) have been critical for development of this report.

The collection of data in the framework of the WHO Global Survey on Alcohol and Health and the development of this report were undertaken in collaboration with the six WHO regional offices and WHO country offices. Key contributors to the report in the WHO regional offices are:

WHO African Region:
Carina Ferreira-Borges, Davison Munodawafa and Hudson Kubwalo

WHO Region of the Americas:
Maristela Monteiro, Jorge J. Rodriguez and Blake Andrea Smith

WHO Eastern Mediterranean Region:
Khalid Saeed
WHO European Region:
Lars Møller and Nina Blinkenberg
WHO South-East Asia Region:
Vijay Chandra and Nazneen Anwar
WHO Western Pacific Region:
Xiangdong Wang and Maribel Villanueva.

For their contributions to individual chapters and annexes we acknowledge the following:

Executive summary: Linda Laatikainen and Maria Renström.

Chapter 1: Linda Laatikainen, Alexandra Fleischmann, Gerhard Gmel, David Jernigan, Vladimir Poznyak, Jürgen Rehm, Dag Rekve, Maria Renström, Margaret Rylett.

Chapter 2: Gerhard Gmel, Florian Labhart, Jürgen Rehm, Margaret Rylett, Kevin Shield.

Chapter 3: Jürgen Rehm, Kevin Shield, Gretchen Stevens.

Chapter 4: David Jernigan and Marissa Esser with contributions from Baigalmaa Dangaa (Mongolia), Melvyn Freeman (South Africa), Ivan Konorazov (Belarus), John Mayeya (Zambia) and Margaret Rylett.

Country Profiles: Alexandra Fleischmann and Margaret Rylett with contributions from Gerhard Gmel, David Jernigan, Vladimir Poznyak, Jürgen Rehm and Dag Rekve.

Appendices 1–3: Margaret Rylett and Alexandra Fleischmann with contribution from Gretchen Stevens.

Appendix 4: Margaret Rylett with contributions from Alexandra Fleischmann, Jürgen Rehm and Gretchen Stevens.

This report would not have been possible without contributions of the WHO national counterparts for implementation of the Global strategy to reduce the harmful use of alcohol in WHO Member States who provided country level data and other relevant information regarding alcohol consumption, alcohol-related harm and policy responses.

The report benefited from the input provided by the following peer reviewers:
Chapter 1: Steve Allsop (Australia), Thomas Babor (USA), Maria Elena Medina-Mora (Mexico), Neo Morojele (South Africa), Esa Österberg (Finland).

Chapters 2 and 3: Guilherme Borges (Mexico), Wei Hao (China), Ralph Hingson (USA), Pia Mäkelä (Finland), Ingeborg Rossow (Norway).

Chapter 4: Bernt Bull (Norway), Maris Jesse (Estonia), Isidore S. Obot (Nigeria), Esa Österberg (Finland), Charles Parry (South Africa).

Susan Kaplan (Switzerland) edited the report.

L'IV Com Sàrl (Switzerland) developed the graphic design and layout.

Administrative support was provided by Divina Maramba and Mary Dillon.

WHO interns who contributed to the report include: Fredrik Ansker, Sally Cruse, Michael Dean, Nina Elberich, Elise Gehring, Wenjing Huang, Angelos Kassianos, Dan Liu, Celine Miyazaki, Even Myrtroen, Eugenie Ng, Ifeoma Onyeka, Derrick Ssewanya, Karin Strodel, Helen Tam-Tham and Christina von Versen.

Finally, WHO gratefully acknowledges the financial support of the Government of Norway for the development and production of this report.

EXECUTIVE SUMMARY

This report provides a global overview of alcohol consumption in relation to public health (Chapter 1) as well as information on: the consumption of alcohol in populations (Chapter 2); the health consequences of alcohol consumption (Chapter 3); and policy responses at national level (Chapter 4). The main messages of these chapters can be summarized as follows:

CHAPTER 1: ALCOHOL AND PUBLIC HEALTH

Alcohol is a psychoactive substance with dependence-producing properties that has been widely used in many cultures for centuries. The harmful use of alcohol causes a large disease, social and economic burden in societies.

- Environmental factors such as economic development, culture, availability of alcohol and the level and effectiveness of alcohol policies are relevant factors in explaining differences and historical trends in alcohol consumption and related harm.
- Alcohol-related harm is determined by the volume of alcohol consumed, the pattern of drinking, and, on rare occasions, the quality of alcohol consumed.
- The harmful use of alcohol is a component cause of more than 200 disease and injury conditions in individuals, most notably alcohol dependence, liver cirrhosis, cancers and injuries.
- The latest causal relationships suggested by research are those between harmful use of alcohol and infectious diseases such as tuberculosis and HIV/AIDS.
- A wide range of global, regional and national policies and actions are in place to reduce the harmful use of alcohol.

CHAPTER 2: ALCOHOL CONSUMPTION

- Worldwide consumption in 2010 was equal to 6.2 litres of pure alcohol consumed per person aged 15 years or older, which translates into 13.5 grams of pure alcohol per day.
- A quarter of this consumption (24.8%) was unrecorded, i.e., homemade alcohol, illegally produced or sold outside normal government controls. Of total recorded alcohol consumed worldwide, 50.1% was consumed in the form of spirits.
- Worldwide 61.7% of the population aged 15 years or older (15+) had not drunk alcohol in the past 12 months. In all WHO regions, females are more often lifetime abstainers than males. There is a considerable variation in prevalence of abstention across WHO regions.

- Worldwide about 16.0% of drinkers aged 15 years or older engage in heavy episodic drinking.
- In general, the greater the economic wealth of a country, the more alcohol is consumed and the smaller the number of abstainers. As a rule, high-income countries have the highest alcohol per capita consumption (APC) and the highest prevalence of heavy episodic drinking among drinkers.

CHAPTER 3: HEALTH CONSEQUENCES

- In 2012, about 3.3 million deaths, or 5.9% of all global deaths, were attributable to alcohol consumption.
- There are significant sex differences in the proportion of global deaths attributable to alcohol, for example, in 2012 7.6% of deaths among males and 4.0% of deaths among females were attributable to alcohol.
- In 2012 139 million DALYs (disability-adjusted life years), or 5.1% of the global burden of disease and injury, were attributable to alcohol consumption.
- There is also wide geographical variation in the proportion of alcohol-attributable deaths and DALYs, with the highest alcohol-attributable fractions reported in the WHO European Region.

CHAPTER 4: ALCOHOL POLICY AND INTERVENTIONS

- Alcohol policies are developed with the aim of reducing harmful use of alcohol and the alcohol-attributable health and social burden in a population and in society. Such policies can be formulated at the global, regional, multinational, national and subnational level.
- Many WHO Member States have demonstrated increased leadership and commitment to reducing harmful use of alcohol in recent years. A higher percentage of the reporting countries indicated having written national alcohol policies and imposing stricter blood alcohol concentration limits in 2012 than in 2008.

The report also contains country profiles for all 194 WHO Member States as well as data tables to support information provided in chapters 2–4 (Appendices I–III) and a section explaining data sources and methods used in this report (Appendix IV).

global status report on alcohol and health

1. Alcohol and public health

1. ALCOHOL AND PUBLIC HEALTH

The protection of the health of populations by preventing and reducing the harmful use of alcohol is a public health priority, and one of the objectives of the World Health Organization (WHO) is to reduce the health and social burden caused by the harmful use of alcohol. The Global strategy to reduce the harmful use of alcohol defines "harmful use" as drinking that causes detrimental health and social consequences for the drinker, the people around the drinker and society at large, as well as the patterns of drinking that are associated with increased risk of adverse health outcomes.[1] The vision of this strategy is to improve the health and social outcomes of individuals, families and communities, considerably reducing morbidity and mortality due to harmful use of alcohol and their ensuing social consequences (WHO, 2010a).

Alcohol is a psychoactive substance with dependence-producing properties. As described in this report, consumption of alcohol and problems related to alcohol vary widely around the world, but the burden of disease and death remains significant in most countries. The harmful use of alcohol ranks among the top five risk factors for disease, disability and death throughout the world (WHO, 2011a; Lim et al., 2012). It is a causal factor in more than 200 disease and injury conditions (as described in Statistical Classification of Diseases and Related Health Problems (ICD) 10th revision, WHO, 1992). Drinking alcohol is associated with a risk of developing such health problems as alcohol dependence, liver cirrhosis, cancers and injuries (WHO, 2004a; Baan et al., 2007; Shield, Parry & Rehm, 2013). The latest causal relationships suggested by research findings are those between alcohol consumption and incidence of infectious diseases such as tuberculosis and HIV/AIDS (Lönnroth et al., 2008; Rehm et al., 2009b; Baliunas et al., 2010) as well as between the harmful use of alcohol and the course of HIV/AIDS (Hendershot et al., 2009; Azar et al., 2010). As described in chapter 3 of this report, the net effect of harmful use of alcohol is approximately 3.3 million deaths each year, even when the beneficial impact of low-risk patterns of alcohol use on some diseases is taken into account. Thus, harmful use of alcohol accounts for 5.9% of all deaths worldwide.

As described in section 1.6 of this chapter, harmful use of alcohol can also have serious social and economic consequences for individuals other than the drinker and for society at large (e.g. Anderson et al., 2006; Sacks et al., 2013).

Despite the large health, social and economic burden associated with harmful use of alcohol, it has remained a relatively low priority in public policy, including in public health policy (see section 1.7). However, recent international policy frameworks and action plans, such as the WHO Global strategy to reduce the harmful use of alcohol and the WHO Global action plan for the prevention and control of noncommunicable diseases (NCDs) 2013–2020 (see section 1.7.2) are expected to shift the political compass towards

1 The word "harmful" in the strategy refers only to public-health effects of alcohol consumption, without prejudice to religious beliefs and cultural norms in any way. The concept of "harmful use of alcohol" in this context is different from "harmful use of alcohol" as a diagnostic category in the ICD-10 Classification of Mental and Behavioural Disorders (WHO, 1992)

an increased focus on the harmful use of alcohol. In fact, since 2008 WHO Member States have already made improvements in several areas of action recommended by the Global strategy to reduce the harmful use of alcohol. In particular, an increased number of Member States reported having written national alcohol policies and taking action to reduce the prevalence of drink–driving, to limit availability of alcohol and to implement restrictions on alcohol marketing. This positive trend is expected to continue as society's ability and willingness to tackle NCDs and their risk factors, including the harmful use of alcohol, is "a precondition for, an outcome of and an indicator of all three dimensions of sustainable development: economic development, environmental sustainability, and social inclusion" (Global NCD Action Plan 2013–2020; WHO, 2013a).

1.1 ALCOHOL CONSUMPTION IN ITS HISTORICAL CONTEXT

The use of alcoholic beverages has been an integral part of many cultures for thousands of years (McGovern, 2009). Prior to the modern era, fermented alcoholic beverages were known in all tribal and village societies except in Australia, Oceania and North America. In societies where there was no aboriginal alcohol consumption, the encounter with alcoholic beverages was often abrupt and highly problematic. Where alcohol was traditionally consumed, production of alcoholic beverages commonly occurred on a small scale as a household or artisanal activity, particularly when and where agricultural surpluses were available. Drinking alcohol was thus often an occasional and communal activity, associated with particular communal festivals (Gumede, 1995; Parry & Bennets, 1998; Room et al., 2002). There are many places in the world today where versions of these traditional patterns originating from tribal and village societies persist (Obot, 2000; Room et al., 2002; Willis, 2006).

Superimposed upon, and often replacing the aforementioned traditional patterns of drinking, are patterns of production and consumption which developed in European empires and during early modern industrialization. These involved new beverages, new modes of production, distribution and promotion, and new drinking customs and institutions (Jernigan, 2000). As distilled spirits became available and transportation improved, alcoholic beverages became a market commodity which was available in all seasons of the year, and at any time during the week. This increased supply and availability often proved disastrous for indigenous economies (Colson & Scudder, 1988) and public health (e.g. Coffey, 1966). The consequences were also often catastrophic elsewhere in the world (Room et al., 2002). By the nineteenth century, leaders of industry were viewing alcohol as a major impediment to industrial livelihoods, which demanded a sober and attentive workforce. Eventually, and with great difficulty, industrializing societies in Europe and elsewhere came to see the flood of alcohol as a substantial social and health problem. In a number of countries, popular social movements to limit drinking and even to prohibit it gained broad membership and eventually political strength. In most of these countries, after a century or more of popular movements and political activity, a new and fairly stable alcohol control structure was put in place (Aaron & Musto, 1981; Room et al., 2002; WHO, 2011a).

Glycyrrhizin attenuates rat ischemic spinal cord injury by suppressing inflammatory cytokines and HMGB1

Gu GONG, Li-bang YUAN, Ling HU, Wei WU, Liang YIN, Jing-li HOU, Ying-hai LIU, Le-shun ZHOU*

Department of Anesthesiology, General Hospital of the People's Liberation Army, Chengdu Military Region, Chengdu 610083, China

Aim: To investigate the neuroprotective effect of glycyrrhizin (Gly) against the ischemic injury of rat spinal cord and the possible role of the nuclear protein high-mobility group box 1 (HMGB1) in the process.
Methods: Male Sprague-Dawley rats were subjected to 45 min aortic occlusion to induce transient lumbar spinal cord ischemia. The motor functions of the animals were assessed according to the modified Tarlov scale. The animals were sacrificed 72 h after reperfusion and the lumbar spinal cord segment (L2–L4) was taken out for histopathological examination and Western blotting analysis. Serum inflammatory cytokine and HMGB1 levels were analyzed using ELISA.
Results: Gly (6 mg/kg) administered intravenously 30 min before inducing the transient lumbar spinal cord ischemia significantly improved the hind-limb motor function scores, and reduced the number of apoptotic neurons, which was accompanied by reduced levels of tumor necrosis factor-α (TNF-α), interleukin-1β (IL-1β) and interleukin-6 (IL-6) in the plasma and injured spinal cord. Moreover, the serum HMGB1 level correlated well with the serum TNF-α, IL-1β and IL-6 levels during the time period of reperfusion.
Conclusion: The results suggest that Gly can attenuate the transient spinal cord ischemic injury in rats via reducing inflammatory cytokines and inhibiting the release of HMGB1.

Keywords: glycyrrhizin; ischemic spinal cord injury; high-mobility group box 1; tumor necrosis factor-α; interleukin-1β; interleukin-6

Acta Pharmacologica Sinica (2012) 33: 11–18; doi: 10.1038/aps.2011.151; published online 12 Dec 2011

Introduction

Ischemic spinal cord injury (ISCI) is a serious complication that can result from thoracoabdominal aortic surgery and can cause paraplegia in 2% to 18% of patients[1, 2]. In a recent report, only 5% of 127 patients who underwent clamp/sew surgery developed paraplegia[3]; paraplegia caused by ISCI remains a problem that should be solved. Multiple studies have suggested that calcium overload, inflammatory processes, free radical production, platelet aggregation, neutrophil accumulation and adhesion following ischemia might contribute to the neuronal damage that was observed in patients with ISCI[4, 5]. However, the cellular and molecular mechanisms of ischemic spinal cord injury are not fully understood. Tumor necrosis factor-α (TNF-α), interleukin-1β (IL-1β) and interleukin-6 (IL-6) are key proinflammatory cytokines that play important functions in the central nervous system during inflammatory injury. Besides causing direct damage to cell membranes, free oxygen radicals activate the accumulation of neutrophils and stimulate various types of cells to produce TNF-α and IL-1β[6]. These cytokines further contribute to the production of other cytokines and to the expression of endothelial leukocyte adhesion factor-1, ultimately leading to endothelial cell damage and spinal cord ischemia[7, 8]. Recent studies have shown that the high-mobility group box 1 (HMGB1) protein, an abundant nuclear protein that acts as an architectural chromatin binding factor, can be passively released by necrotic or damaged cells and serves as a signaling molecule that is involved in acute and chronic inflammation[9, 10]. A wealth of evidence indicates that HMGB1 is massively released during the excitotoxicity-induced, acute damaging process in the post-ischemic brain, where it triggers inflammatory processes, and suggests that HMGB1 acts as a novel mediator that links excitotoxicity-induced acute damage and subsequent inflammatory processes in the post-ischemic brain[11–13].

Along these lines, we have recently recognized glycyrrhizin (Gly), a natural triterpene glycoconjugate that is derived from the root of licorice (*Glycyrrhiza glabra*), as an additional HMGB1 inhibitor. Gly binds directly to both HMG boxes in

Received 2011-07-07 Accepted 2011-10-12

HMGB1, thereby inhibiting its chemoattractant functions in fibroblasts and smooth muscle cells[14, 15]. Of note, Gly is a natural compound that is commonly used in Japan to treat patients with chronic hepatitis[16]; however, no study has been designed to examine its use in preventing ISCI.

The current study was designed to investigate the protective efficacy and dose-response relationship of Gly against the neurologic and histopathological outcomes of spinal cord ischemia and reperfusion injury that are related to aortic occlusion in rats, and to determine whether HMGB1 plays a pathogenetic role in ischemic spinal cord injury. First, we injected ischemic rats with either glycyrrhizin or a placebo. Second, we monitored the concentration of HMGB1, TNF-α, IL-1β, and IL-6 in the plasma of the rats. Third, we detected the expression of HMGB1 and cell death within the ischemic spinal cords of those rats.

Materials and methods

Animals and groups

Male Sprague-Dawley rats weighing 300–350 g were obtained from the Experimental Animal Center of Sichuan University (Chengdu, China) and were allowed free access to laboratory chow and tap water in day-night regulated quarters at 25 °C.

Rats were randomized into the following three experimental groups, each consisting of 15 animals: (i) ISCI rats that were pretreated with saline (NS group); (ii) ISCI rats that were pretreated with Gly (Minophagen Pharmaceutical Co, Tokyo, Japan) at a dose of 6 mg/kg (Gly group); and (iii) healthy, control, sham-operated rats (Sham group). In the pretreatment groups, glycyrrhizin or saline was administered intravenously via the tail vein 30 min before the induction of ischemia/reperfusion (I/R) ISCI.

Experimental I/R spinal cord injury

The detailed surgical method for transient lumbar spinal cord ischemia has been described previously[17]. Briefly, rats were initially anesthetized with intramuscular ketamine (50 mg/kg) and then by a half dose of ketamine, as required for the procedure. During the surgery, body temperature was monitored using a rectal probe and was maintained at 35.5–37.5 °C with a heat lamp. During the procedure, an intravenous catheter was placed into the tail vein, and 0.9% NaCl was infused. Cefazolin was injected intravenously at a single dose of 10 mg/kg immediately before the surgery to prevent infection. To monitor proximal and distal aortal blood pressures, catheters were surgically placed into the left common carotid artery and the left femoral artery, respectively. The abdominal aorta was accessed through a midline laparotomy, and animals in the sham group were subjected to laparotomy without aortic occlusion. For the other groups, animals were subjected to 45 min of cross clamping, where vascular clamps were placed under the left renal vein and above the bifurcation in the aorta. Each rat received 150 IU/kg of heparin before aortic occlusion, the aortic clamps were removed after 45 min, and the abdomen was closed appropriately. Animals were allowed to recover in a plastic box at 28 °C for 3 h and were subsequently placed in their cages with free access to food and water. The Crede maneuver was used twice daily to empty the urinary bladders of paraplegic animals. Animals that never recovered completely from the surgery and died within 24 h after reperfusion were excluded from the analyses.

Serum detection

Blood samples (0.4 mL) were collected from the femoral vein at 0 h, 0.5 h, 2 h, 6 h, 12 h, 24 h, 48 h, and 72 h after reperfusion. Serum was isolated from the blood after centrifugation at 1500 r/min for 15 min and was frozen at -80 °C until enzyme-linked immunosorbent assay (ELISA) analyses were performed. HMGB1 concentrations and the levels of inflammatory mediators (TNF-α, IL-1β, and IL-6) in the serum samples were quantified using specific ELISA kits for rats according to the manufacturers' instructions (Biosource International Inc, Camarillo, CA, USA).

Neurological assessment

The motor functions of the rats were assessed at 24 h, 48 h, and 72 h after the procedure using the following modified Tarlov scale[6, 17, 18]: 0, no voluntary movement (complete paraplegia); 1, perceptible movement at the joint; 2, good joint mobility but unable to stand; 3, ability to stand but unable to walk; 4, weak walking; 5, complete recovery.

Spinal cord HMGB1 contents

The lumbar enlargements of the spinal cords of rats that were killed at the completion of behavioral testing were removed. Five samples from every group were stored at -80 °C until Western blotting analyses were performed. Briefly, frozen samples were mechanically lysed in a homogenization buffer on ice. The lysates were centrifuged at 12000 r/min for 20 min at 4 °C, and the protein concentrations were estimated using a BCA protein assay kit (Jiancheng Bioengineering Institute, Nanjing, China). Each sample was adjusted to a final total protein concentration of 5 μg/μL in 4×sample buffer, heated at 95 °C for 10 min, and then stored at -20 °C. Protein samples (50 μg per lane) were loaded into a 12% SDS-PAGE gel and run at 100 V for 120 min in running buffer. Proteins were then transferred from the gel to a PVDF membrane at 250 mA for 90 min using transfer buffer. The membrane was blocked with 5% skimmed milk for 2 h at room temperature and incubated overnight at 4 °C with primary antibody directed against HMGB1 (Santa Cruz Biotechnology, Santa Cruz, CA, USA) at a dilution of 1:500. Glyceraldehyde-3-phosphate dehydrogenase (GAPDH) (diluted in 1:6000, Sigma-Aldrich Inc, St Louis, MO, USA) was used as a loading control. After 6×10 min rinses with PBS/Tween, the membrane was incubated in the appropriate HRP-conjugated secondary antibody (diluted 1:1000 in PBST) for 2 h. The blotted protein bands were visualized using enhanced chemiluminescence (ECL) Western blotting detection reagents (Millipore, Billerica, MA, USA), and the blots were exposed to X-ray film. Developed films were digitized using an Epson Perfection 2480 scanner (Seiko, Nagano, Japan), and optical densities were obtained

using Glyko Bandscan software (Glyko, Novato, CA, USA). All experiments were repeated at least three times.

Histological examination

The remnant samples (n=10 for each group) were fixed in 10% formalin, embedded in paraffin and cut to a thickness of 6 μm, with a routine follow-up procedure. An observer who was uninformed of the experimental conditions of the animals recorded the data.

Coronal sections were stained with hematoxylin and eosin (HE) for light microscopic examination. Changes in rat motor neurons caused by ischemia were identified to be shrunken cellular bodies, a disappearance of Nissl granules, an intensely eosinophilic cytoplasm and triangular and pyknotic nuclei. The remaining normal neurons in the ischemic ventral spinal cord of each animal, as judged by their morphological appearance, were counted in three sections that were selected randomly from the rostral, middle, and caudal levels of the L4 segment and then averaged. The numbers of normal neurons per section of the anterior spinal cords of the rats (anterior to an imaginary line drawn through the central canal, which was perpendicular to the vertical axis) were compared between three groups.

TUNEL (terminal deoxynucleotidyl transferase dUTP nick-end labeling) reactions were applied to identify cells with fragmented DNA according to the instruction manual of a commercial TUNEL kit (Roche, Basel, Switzerland). Cell viability was assessed by visual inspection of damaged cells that had been stained with TUNEL, and data are presented as the number of TUNEL-positive cells from three sections of the same animal.

Statistical analysis

All data, except neurologic scoring, were presented as the mean±SEM (standard error of mean), which was calculated using SPSS (Statistical Package for the Social Sciences) 12.0 software (SPSS Inc, Chicago, IL, USA). The Mann-Whitney U-test was used to compare the behavior and activity score among groups, and the concentrations of serum HMGB1 and inflammatory mediators were analyzed using two-way repeated-measures (time and group) analysis of variance followed by the *post hoc* Student-Newman-Keuls test. Correlations between HMGB1 levels and concentrations of inflammatory mediators were analyzed using Spearman's rank correlation test, and the number of normal neurons and TUNEL-positive motor neurons in the anterior spinal cord were analyzed using the Kruskal-Wallis test followed by the Mann-Whitney U-test with the Bonferroni correction. The P<0.05 level of probability was used as the criteria for significance.

Results

Serum HMGB1 concentrations

As shown in Figure 1, the HMGB1 serum concentrations in the sham animals were unchanged during the period of the experimental procedure. However, the concentrations of HMGB1 in the serum of the NS and Gly groups significantly increased

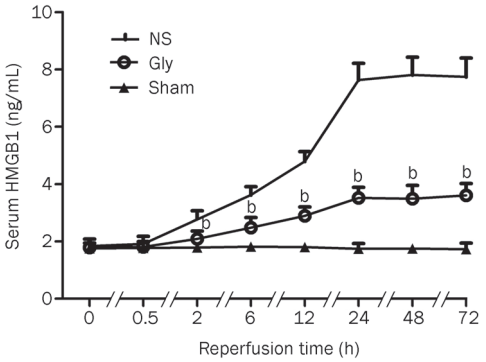

Figure 1. Time course of serum HMGB1 concentrations. The serum HMGB1 levels were significantly increased after spinal cord ischemia-reperfusion compared with that of preischemia (P<0.05), whereas they were significantly decreased in the animals treated by Gly compared with that of animals in NS group (P<0.05). Data are means±SEM. n=15 for each group. ^bP<0.05 *vs* NS group.

2 h after reperfusion, when compared to pre-ischemia levels, and the concentrations remained at higher levels thereafter (P<0.05). Furthermore, HMGB1 serum concentrations in the animals that were treated with Gly were significantly lower than in those of the NS group from 2 h to 72 h after reperfusion (P<0.05).

Concentrations of inflammatory cytokines in the serum

The concentrations of TNF-α, IL-1β, and IL-6 were low in the serum of the rat sham group (Figure 2); however, serum levels of these inflammatory cytokines were greatly induced from 6 h to 72 h after reperfusion in the experimental groups (P<0.05). As shown in Figure 2, Gly administration before I/R resulted in significantly decreased IL-1β, TNF-α, and IL-6 concentrations compared to the NS group (P<0.05). Moreover, the serum HMGB1 contents correlated well with the levels of TNF-α (r=0.947), IL-1β (r=0.906), and IL-6 (r=0.935) at 2 h, 6 h, 12 h, 24 h, 48 h, and 72 h after reperfusion (Figure 3).

Neurologic outcomes

All animals survived until the final neurologic behavior assessments at 24 h, 48 h, and 72 h after reperfusion. The hind-limb motor function scores of the 3 groups at 24 h, 48 h, and 72 h after reperfusion are shown in Table 1. In the NS group, most of the animals developed complete paraplegia of the hind-limbs (grade 1) at 72 h after reperfusion. Importantly, the neurologic statuses of members of the Gly group were signifi-

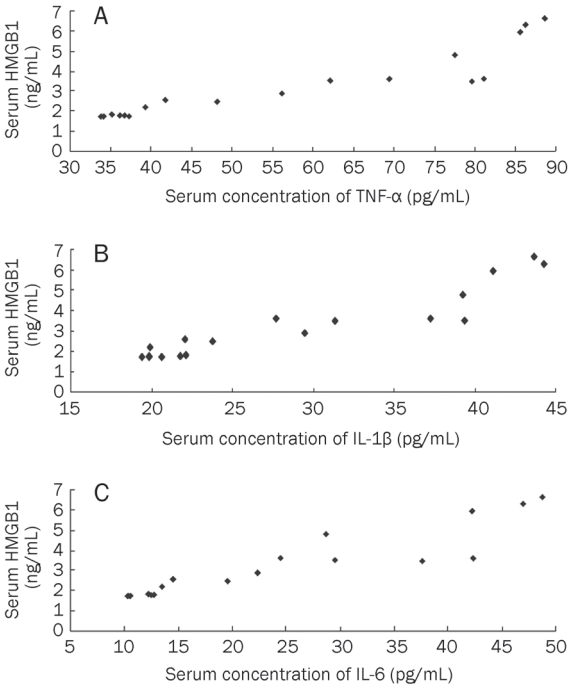

Figure 3. The serum HMGB1 contents correlated well with the levels of TNF-α (r=0.947, *P*=0.004), IL-1β (*r*=0.906, *P*=0.000), and IL-6 (*r*=0.935, *P*=0.000) at 2 h, 6 h, 12 h, 24 h, 48 h, and 72 h after reperfusion. *n*=17 pairs.

cantly improved, compared to those of the NS group, at 24 h, 48 h, and 72 h after reperfusion (*P*=0.029, 0.001, 0.004, respectively).

Western blotting

The protein levels of HMGB1 were detected by Western blot analysis (Figure 4). The protein was expressed at low levels in the spinal cords of the sham group members; however, the levels of HMGB1 significantly increased in the spinal cords of members of the experimental groups as compared with HMGB1 levels of the sham groups (*P*=0.006). Furthermore, the protein expression of HMGB1 in the spinal cords of members of the Gly group was significantly lower than that of the NS group (*P*=0.035).

Histological examination

The representative micrographs of HE staining of the ventral horn of the L4 spinal cord segment 72 h after reperfusion are shown in Figure 5A–5C. The number of normal cells in the Gly group was more than that in the NS group (Figure 5D, *P*=0.019), and TUNEL staining identified a few dead cells in the cord sections of the sham-operated animals (Figure 6A). In the spinal cords of members of the NS group, numerous cells were strongly positive for TUNEL staining (Figure 6B). However, in samples from the Gly group, only a few cells were positive for TUNEL staining (Figure 6C). For quantitative measurement, the number of cells that were positive or negative for TUNEL was recorded for each specimen in a blind fashion. Administration of Gly 30 min before ischemia significantly reduced the total number of dead cells, compared to that of the NS group (Figure 6D, *P*=0.016). Moreover, the

number of dead cells correlated well with the HMGB1 levels in spinal cord tissue at 72 h after reperfusion (Figure 6E, n=15 pairs, r=0.929, P=0.005).

Discussion

There is a wealth of evidence to suggest that the systemic inflammatory response that is associated with I/R injury contributes to the morbidity and mortality that is associated with the repair of thoracoabdominal aortic aneurysms[19]. The principal mechanisms of pharmacological therapy, such as the administration of high doses of the glucocorticoid steroid methylprednisolone that are used in humans, are likely to inhibit posttraumatic lipid peroxidation and inflammatory responses. In this study, we show that Gly significantly atten-

uated spinal cord I/R injury when administered 30 min before ischemia, and this protection was accompanied by a reduction in serum inflammatory factors and the protein HMGB1.

HMGB1 is a non-histone, nuclear protein with dual functions. Inside cells, HMGB1 binds DNA and plays a role in transcriptional regulation. Outside cells, HMGB1 serves as a late cytokine-like mediator of systemic inflammation[20]. HMGB1 can activate inflammatory pathways when released from ischemic cells, and studies indicate that HMGB1 acts as an early mediator of inflammation and organ damage in hepatic I/R injury. HMGB1 levels were increased during liver I/R as early as 1 h after reperfusion and then further increased, in a time-dependent manner, up to 24 h. Inhibition of HMGB1 activity with a neutralizing antibody significantly decreased liver damage after I/R, whereas administration of recombinant HMGB1 worsened I/R injury[21, 22]. Moreover, HMGB1 is massively released extracellularly and plays a cytokine-like function in the postischemic brain[11, 12]. HMGB1, as a mediator of postischemic brain damage, plays a critical role in the development of brain infarction through the amplification of plural inflammatory responses in the ischemic region and could be an outstandingly suitable target for treatment for this damage[23]. Intravenous injection of a neutralizing, anti-HMGB1 monoclonal antibody provides a novel therapeutic strategy for ischemic stroke[24]. In addition, serum HMGB1 levels were significantly elevated in patients with myocardial ischemia and cerebral ischemia, suggesting that systemic HMGB1 levels are elevated in human ischemic disease[25]. In this study, serum HMGB1 concentrations and levels of IL-β, TNF-α, and IL-6 increased during spinal cord I/R as early as 2 h after reperfusion and in a time-dependent manner up to 72 h. These results indicate that HMGB1 is involved in the proinflammatory stress response to I/R injuries of the spinal cord in a time-dependent manner after spinal cord I/R in rats.

Obviously, inhibition of HMGB1 secretion or release represents a novel and promising strategy for the therapy of I/R injuries[23]. A growing amount of information implicates a possible responsibility of inflammatory mediators in the pathogenesis of spinal cord injury. In a rat model of traumatic SCI, the tissue level of TNF-α in the spinal cord significantly increased 24 h after injury[26]. Similarly, in a mouse model of traumatic SCI, TNF-α, and IL-1β were produced almost immediately following injury, and this production was followed by the expression of IL-6[27]. Clinical research has also revealed increased immunoreactivity of TNF-α, IL-1β, and IL-6 in neurons at both early and late phases of trauma in human spinal cord tissues after injury[28]. In the present study, we demonstrated that serum proinflammatory cytokine levels (TNF-α, IL-1β, and IL-6) significantly increased after spinal cord I/R in rats. These increases were accompanied by elevated HMGB1 concentrations, and by analyzing histopathological specimens, tissue damage to the spinal cord was evident. In the NS group, all three proinflammatory cytokine levels reached significantly higher levels when compared to the sham-operated group, and these elevated levels were relieved by treatment with Gly. Treatment with Gly attenuated serum HMGB1 levels after spinal cord I/R injury when the drug was administered 30 min before ischemia. Moreover, the HMGB1 contents of spinal cord tissue in animals that had been treated with Gly 72 h after reperfusion were found to be significantly lower than those of the controls. To the best of our knowledge, this is the first study to demonstrate a protective effect of Gly that is related to its inhibitory effect on HMGB1 release in spinal cord I/R injuries. We found that I/R upregulated the expression of HMGB1 in injured tissue and the levels of IL-β, TNF-α, and IL-6 in the peripheral blood, which was inhibited by Gly administration. These results suggest that I/R could activate HMGB1, which might play a central role in the inflammatory response that leads to secondary insults after ischemia. Therefore, the therapeutic benefit of pre-I/R Gly administration might be due to its salutary effect on modulating HMGB1.

However, apoptosis has been demonstrated to be an important mechanism of neuron death in the ischemic spinal cord, and to play an important role in delayed paraplegia in the animal model of aortic occlusion[29]. It is important to note that the TUNEL assay does not distinguish between cell death mechanisms (necrosis or apoptosis); however, this method is useful for detecting damaged cells using light or fluorescence microscopy[30]. Furthermore, histopathological examinations of the spinal cords in our study revealed that there was significant neuronal loss in both 72-h I/R groups, when compared to the sham-operated groups. In this study, dead cells were detected based on positive TUNEL staining because the fluorescent nucleus developed a granular pattern. We used this method because of its high sensitivity and specific means of identifying DNA fragmentation. As noted, numerous dead cells were observed in the spinal cords of the control animals, and the total number of TUNEL-positive cells was reduced significantly after Gly treatment. The results showed that Gly alleviated cell apoptosis that was induced by spinal cord I/R. In line with this, the animals that were treated with Gly had better neurologic outcomes than those of the NS group. Moreover, at 72 h after reperfusion, the HMGB1 levels in spinal cord tissue from animals that had been treated with Gly were significantly lower than those of the NS group, and these levels correlated well with the numbers of dead cells in the spinal cord 72 h after reperfusion. Together, these results indicate that inhibiting the release of HMGB1 with Gly results in less tissue damage and better functional recovery of neurons. In accordance with our experimental results, the relationship between apoptosis and HMGB1 release in macrophages and other cells was investigated in an *in vitro* study, and those results indicated that the release of HMGB1 from macrophages correlated with the occurrence of apoptosis, and suggested that these processes reflected common mechanisms and could occur concomitantly[31]. However, other studies have shown that HMGB1 production occurred downstream of apoptosis in the final common pathway to organ damage in severe sepsis[32]. Thus, the crosstalk between HMGB1 and apoptosis must be further explored.

Because there are two contradictory pathways for inflammation and apoptosis, it is interesting that Gly influences the two

pathways simultaneously. Here, two mechanisms could be considered to cause this result. First, Gly could inhibit inflammation by suppressing HMGB1 expression. HMGB1 has been thought to take part in anti-inflammation because it activates inflammatory responses through multiple pathways, including activating the MAPK pathway and then NF-κB translocation, which triggers inflammatory responses[33]. These pathways lead to a cascade of inflammatory responses that can cause tissue damage and the release of inflammatory mediators. Secondly, the TUNEL assay is only useful for detecting dead cells, and this method does not distinguish between cell death mechanisms (necrosis or apoptosis)[30]. Because inflammatory responses can cause tissue damage and even death, Gly could reduce the number of TUNEL-positive cells by suppressing HMGB1 expression in this study. A limitation to our present study is that we did not assay the mechanism of Gly in attenuating cell damage.

In conclusion, our results confirmed that HMGB1 release plays an important role in spinal cord I/R damage[34], and we showed the Gly affords strong protection against transient spinal cord I/R injury by reducing inflammatory factors and cell apoptosis. Moreover, this protective effect by Gly is related to the inhibition of HMGB1 release that is induced by spinal cord I/R. These data suggest a new therapeutic possibility for treating ISCI with Gly. Future research should be directed toward developing a better understanding of the crosstalk between HMGB1 and apoptosis, as this ultimately might lead to therapeutic strategies for humans.

Abstract

Aim: Glycyrrhizin (GL) has been reported to protect against ischemia and reperfusion (I/R)-induced injury by inhibiting the cytokine activity of high mobility group box 1 (HMGB1). In the present study, the protective effects of GL against I/R injury, as well as the related molecular mechanisms, were investigated in rat brains.

Methods: Focal cerebral I/R injury was induced by intraluminal filamentous occlusion of the middle cerebral artery (MCA) in Male Sprague-Dawley rats. GL alone or GL and rHMGB1 were administered intravenously at the time of reperfusion. Serum levels of HMGB1 and inflammatory mediators were quantified via enzyme-linked immunosorbent assay (ELISA). Histopathological examination, immunofluorescence, RT-PCR and western blotting analyses were performed to investigate the protective and anti-apoptotic effects and related molecular mechanisms of GL against I/R injury in rat brains.

Results: Pre-treatment with GL significantly reduced infarct volume and improved the accompanying neurological deficits in locomotor function. The release of HMGB1 from the cerebral cortex into the serum was inhibited by GL administration. Moreover, pre-treatment with GL alleviated apoptotic injury resulting from cerebral I/R through the inhibition of cytochrome C release and caspase 3 activity. The expression levels of inflammation- and oxidative stress-related molecules including TNF-α, iNOS, IL-1β, and IL-6, which were over-expressed in I/R, were decreased by GL. P38 and P-JNK signalling were involved in this process. All of the protective effects of GL could be reversed by rHMGB1 administration.

Conclusions: GL has a protective effect on ischemia-reperfusion injury in rat brains through the inhibition of inflammation, oxidative stress and apoptotic injury by antagonising the cytokine activity of HMGB1.

Introduction

Ischemic stroke remains one of the leading cause of death and disability worldwide. Recent insight into the basic mechanism involved in ischemic stroke indicates that endothelial dysfunctions along with oxidative stress and neuroinflammation represent key elements in the occurrence and development of ischemic brain damage that results in cell damage and death [1,2]. Within hours of the ischemic insult, infiltrating leukocytes, as well as resident brain cells including neurons and glia, may release pro-inflammatory mediators such as cytokines, chemokines, and oxygen/nitrogen free radicals that contribute to the evolution of tissue damage [3]. Furthermore, the cerebral ischemia that occurs in brain cells affected by a stroke triggers a complex array of molecular and cellular alterations including the activation of signalling pathways that may either contribute to neuronal damage or protect neurons. Mitogen-activated protein kinases (MAPKs) have crucial roles in signal transduction from the cell surface to the nucleus and regulate cell death and survival processes. Among the MAPK pathways known to be activated in neurons in response to ischemia are the JNK, ERK, and p38 MAPK pathways [4,5].

High mobility group box 1 (HMGB1), a ubiquitous and abundant nuclear protein, can either be passively released into the extracellular milieu in response to necrotic signals or actively secreted in response to inflammatory signals [6–8]. Recently, HMGB1 has been reported to be a potent pro-inflammatory cytokine-like factor that contributes to the pathogenesis of vasculature and connects excitotoxicity-induced acute damage

processes with delayed inflammatory processes in the post-ischemic brain [9,10]. The receptor for advanced glycation end products (RAGE), one of the most important receptors for HMGB1, functions as a sensor of necrotic cell death, and the HMGB1–RAGE signalling axis contributes to inflammation and ischemic brain damage [11]. Intravenous injection of neutralising anti-HMGB1 mAb or intranasal delivery of HMGB1 siRNA conferred robust neuroprotection in the post-ischemic brain by antagonising the pro-inflammatory function of HMGB1 [12,13].

Glycyrrhizin (GL) is a major active constituent of *Glycyrrhiza glabra* root and is composed of a molecule of glycyrrhizic acid and two molecules of glucuronic acid. This compound has been associated with numerous pharmacological effects, including anti-inflammatory, anti-viral, anti-tumour, and hepatoprotective activities, and is commonly used in Asia to treat patients with chronic hepatitis [14–17]. It was reported by Sitia et al [18] that, as an HMGB1 inhibitor, GL binds directly to HMGB1 (Kd ~150 μM), interacting with two shallow concave surfaces formed by the two arms of both HMG boxes. GL has been reported to protect from I/R-induced injury in many organs, including the liver [19], spinal cord [20] and heart [21], by inhibiting the chemoattractant and mitogenic functions of HMGB1. Recently, a robust neuroprotective effect of Stronger Neo-Minophagen C (SNMC), a GL-containing preparation, has been reported in the post-ischemic brain, and this neuroprotective effect is due, at least in part, to an anti-inflammatory effect [22]. However, it is not known if the neuroprotective effect of GL occurs through the antagonism of HMGB1 and the ensuing molecular signalling events. Therefore, the aim of this study was to investigate the potential protective effect of GL, as well as the related mechanisms, against I/R injury in the rat brain, mainly in relation to the following aspects: (1) the neuroprotective effects of GL on focal cerebral ischemia; (2) the release of HMGB1 in rat serum and brain; (3) the effect of GL on the alleviation of apoptosis caused by I/R injury; (4) the expression of HMGB1-dependent inflammation- and oxidative stress-related molecules; (5) the involvement of certain MAPK pathways that are modulated by GL.

Materials and Methods

Animals and groups

All experiments were performed in accordance with the "Guide for the Care and Use of Laboratory Animals" published by the US NIH (National Institutes of Health Publication No. 85-23, revised 1996) and were approved by the Committee on Animal Experiments of the Sichuan Neurosurgical Institute. Male Sprague-Dawley rats weighing 325±25 g were obtained from the Experimental Animal Centre of the Sichuan Neurosurgical Institute (China) and were allowed free access to laboratory chow and tap water in day-night quarters at 25°C. Rats were randomly divided into the following four experimental groups of 8 animals each: (1) healthy control, sham-operated rats (the sham group); (2) I/R rats pre-treated with saline (the NS group); (3,4,5) I/R rats pre-treated with GL separately at doses of 2 mg/kg, 4 mg/kg and 10 mg/kg (the 2 mg/kg, 4 mg/kg and 10 mg/kg GL groups); (6) I/R rats pre-treated with GL and recombinant HMGB1 (100 μg per rat) (the GL+rHMGB1 group). In the pre-treatment groups, after 30 min ischemia and before reperfusion, NS, GL or GL plus rHMGB1 was administered intravenously in the tail vein in a volume of 0.5 ml followed by a 48 h reperfusion.

Focal cerebral I/R

Focal cerebral ischemia was induced by performing intraluminal filamentous occlusion of the middle cerebral artery (MCA) for 60 min, according to methods that have been described previously [23]. After 60 min of MCA occlusion, reperfusion of the MCA was initiated by removing the MCA-occlusive filament. The right femoral artery was cannulated to monitor mean arterial blood pressure, arterial blood gases, and pH. Regional cerebral blood flow was monitored using a laser Doppler flowmeter (Periflux System 5000; Perimed, Jarfalla, Sweden). A thermoregulated heating pad and an overhead heating lamp were used to maintain a rectal temperature of 37±0.5°C. In sham-operated rats, an incision was made over the MCA, but the artery was not occluded. The cerebral I/R injury model was developed with 60 min of MCA occlusion followed by 48 h reperfusion.

Triphenyltetrazolium chloride (TTC) staining and infarct volume assessments

Coronal brain sections (2-mm thickness) were incubated with 2% TTC at 37°C for 30 min with gentle shaking and then fixed with 10% formalin in PBS. The stained slices were photographed, and the size of the infarct was quantified using NIH image software.

TTC staining was used to measure infarction volumes two days after I/R (n = 8 per group) and whole brains were dissected coronally into 2-mm brain slices. Two investigators blinded to the study protocol measured the infarct sizes with a computerised image analyser. To account for cerebral oedema and differential shrinkage resulting from tissue processing, the areas of ischemic lesions were determined by subtracting the areas in ipsilateral hemispheres from those of contralateral hemispheres. Infarct volumes were calculated (in mm^3) by multiplying the summed section infarct areas by the section thickness.

Evaluation of neurological deficits

Neurological deficits were evaluated by two methods. In the rota-rod test, rats were conditioned for 3 days before MCA occlusion on an accelerating rota-rod cylinder at 5 to 15 rpm. Rats that could stay on the rotating rod at 15 rpm for 180 s were subjected to MCA occlusion. After MCA occlusion, each rat was subjected to trials conducted at 3 different speeds (5, 10 and 15 rpm), and the mean duration of three trials at each speed on the rota-rod was recorded. The other test was a neurological scoring method, which was performed essentially as described by Bederson et al [24]. The scores were categorised according to four grades (0, normal; 1, moderate; 2, considerable; 3, severe). The modified Neurological Severity Scores system consists of motor, sensory, balance, and reflex tests, all of which are graded using a scale of 0–18 (normal: 0, maximal deficit: 18). The neurological evaluation was performed by an investigator who was blind to the treatment condition.

Serum ELISA detection

Blood samples (0.5 ml) were collected from the femoral vein at 6, 12, 24 and 48 h after reperfusion. Serum was isolated from the blood after centrifugation at 14 000 rpm for 20 min at 4°C. After centrifugation, serum was frozen at −80°C until enzyme-linked immunosorbent assay (ELISA) analyses were performed. HMGB1 concentrations and the levels of inflammatory mediators (TNF-α, iNOS,IL-1β, COX-2 and IL-6) in the serum samples were quantified using specific ELISA kits for rats according to the manufacturer's instructions (Biosource International Inc., Camarillo, CA, USA).

Western blot

Total protein extracts or detached subcellular fractions from rat cerebral tissue were prepared as described previously [25]. The antibodies and the dilutions were as follows: p-JNK No. 9255 (1:2000), t-JNK No. 9252 (1:1000), p-ERK [1/2] No. 9101 (1:1000), t-ERK [1/2] No. 4695 (1:1000), p-p38 No. 9211(1:1000), t-p38 No. 9212 (1:1000) (Cell Signaling Technology, Danvers, Mass), Cytochrome c (1 μg/ml, No. ab90529, Abcam Plc., Cambridge, UK) and HMGB1 (1 μg/ml, No. ab18256, Abcam Plc., Cambridge, UK). Horseradish peroxidase–coupled rabbit and mouse IgG (1:2000) were used as secondary antibodies. Proteins were separated on 10–20% SDS polyacrylamide gels and electrophoretically transferred to polyvinylidene difluoride membranes, which were then incubated overnight at 4°C with the primary antibody diluted in blocking solution. After washing, membranes were treated with horseradish peroxidase-conjugated secondary antibodies and then with enhanced chemiluminescence reagent (Amersham Biosciences, Piscataway, NJ). The film was scanned with a GS-700 imaging densitometer (Bio-Rad Laboratories, Hercules, CA), and the results were quantified with Multi-Analyst software (Bio-Rad Laboratories).

RNA preparation and reverse transcription-PCR

Total RNA was prepared using Trizol reagent (Invitrogen, Gaithersburg, MD) according to the manufacturer's instructions, and 1 μg RNA samples were used for cDNA synthesis. First-strand cDNA synthesis was primed with random hexamers and conducted according to the manufacturer's specifications (RT-PCR kit; Roche, Mannheim, Germany). cDNA equivalent to 200 ng of total RNA was subjected to PCR using the manufacturer's protocol (PCR core kit; Roche). The sense and antisense primers used for the analysis of rat HMGB1, TNF-α, IL-1β, iNOS, COX-2, IL-6 and GAPDH expression were as follows. HMGB1: 5′-CTGATGCAGCTTA TACGAAG-3′ and 5′-TCAGGTAAGGAGCAGAACAT- 3′ (460 bp). TNF-α: 5′-CCC CTTTATCGTCTACTCCTC-3′ and 5′-GCTGGTAGTTTAGCTCCGTTT-3′ (553 bp). IL-1β: 5′-TCATTGTGGCTGTGGAGAAG-3′ and 5′-CTATGTCCCGACCATTGCTG-3′ (579 bp). iNOS: 5′-GCATCCCAAGTACGAGTGGT-3′ and 5′-GAAGGCGTAG CTGAACAAGG-3′ (700 bp). COX-2: 5′-GTGGGATGACGAGCGACTGT-3′ and 5′ -TTTCAGGGAGAAGCGTTTGC-3′ (454 bp). IL-6: 5′-GGATACCACCCACAACAGAC-3′ and 5′-TTGCCGAGTAGACCTCATAG-3′ (520 bp). GAPDH: 5′-CCATCAC TGCCACTCAGAAGA-3′ and 5′-CATGAGGTCCACCACCCTGT- 3′ (446 bp). The annealing temperature was 55°C for all primer pairs.

Immunofluorescence and TUNEL staining

Brains were isolated and fixed with 4% paraformaldehyde by transcardial perfusion and post-fixed in the same solution overnight at 4°C. Coronal brain sections (20 μm) from the ischemic core region were prepared using a vibratome (Leica, Solms, Germany), and immunological staining was performed using a previously described floating method [26]. Rabbit anti-HMGB1 (ab18956; Abcam, Cambridge, UK) antibody was used at a 1:500 dilution. FITC-labelled anti-rabbit IgG (Jackson ImmunoResearch Laboratories, West Grove, PA) was used as a secondary antibody for anti-HMGB1.

The terminal deoxynucleotidyl transferase-mediated dUTP-biotin nick end labelling (TUNEL) assay was carried out with a commercial TUNEL kit (Roche, Switzerland) according to the manufacturer's instructions. Apoptotic cells in the rat heart after I/R in each group were counted separately using Image J software.

Analysis of superoxide and peroxynitrite formation

The oxidative fluorescent dye dihydroethidium (DHE; Sigma-Aldrich) was used to evaluate in situ superoxide production [27]. Frozen, enzymatically intact brains from the ischemic core region were cut into 30-μm thick sections and placed on glass slides. The sections were simultaneously incubated with DHE (10 μmol/L) in phosphate-buffered saline for 30 min at 37°C, in a humidified chamber that was shielded from light. We also monitored peroxynitrite formation by detecting nitrosylated tyrosine residues on proteins. We performed immunostaining with an anti-3-nitrotyrosine (3-NT) antibody (1:1000; Upstate Biotechnology). Coronal sections cut through the striatum (3 sections per brain, 1 mm in width) were imaged in parallel. Superoxide or 3-NT–positive cells were manually counted in the eight regions around the striatum under ×100 magnification using a laser scanning confocal microscope equipped with a Bio-Rad MRC 1024 (argon and krypton).

Measurement of lipid peroxidation

Malondialdehyde (MDA) was estimated as an indicator of lipid peroxidation (n = 8 per group). Brain tissues were homogenised with sodium phosphate buffer (pH 7.4). The reagents (1.5 ml acetic acid, 1.5 ml thiobarbituric acid, and 0.2 ml sodium dodecyl sulphate) were added to 0.1 ml of processed tissue sample. The mixture was then heated at 100°C for 60 min. The mixture was cooled with tap water and 5 ml of n-butanol:pyridine (15:1), and 1 ml of distilled water was added. After centrifugation at 4000 rpm for 10 min, the organic layer was withdrawn and the absorbance was measured at 532 nm using a spectrophotometer.

Statistical analysis

All data were expressed as the means±SEM (standard error of the mean). SPSS 17.0 was used for statistical analysis of the data. The concentrations of serum HMGB1 and inflammatory mediators were analysed using two-way repeated measures (time and group) analysis of variance followed by the post hoc Student-Newman-Keuls test. The significance level was set at $p<0.05$.

Results

Neuroprotective effects of GL on focal cerebral ischemia

No damage was observed upon TTC staining in the cerebrums of sham-group rats, whereas MCA occlusion for 60 min in rats produced massive infarction 48 h after reperfusion. Pre-treatment with different concentrations of GL significantly reduced the infarct volumes in a dose-dependent manner in focal cerebral I/R rats. There were no significant differences between the infarct volumes of the 4 mg/kg and 10 mg/kg GL-pre-treatment groups. Hence, a dose of 4 mg/kg of GL was selected for subsequent experiments, considering the potential for drug toxicity (Figure 1A).

High Neurological Severity Scores in the NS rats persisted for up to 48 h. Consistent with the reduced infarct volumes, when 4 mg/kg GL was administered at 30 min after ischemia and before reperfusion, the mean modified Neurological Severity Scores were significantly lower than those of rats in the PBS-treated NS group from 6 h to 48 h. From 6 h to 24 h, the Neurological Severity Scores declined slowly and reached the minimum value at 48 h after reperfusion in the GL group (Figure 1B). Motor activities were assessed using the rota-rod test at 5, 10 or 15 rpm speed loads. Pre-treatment with 4 mg/kg GL markedly improved the neurological deficits observed on the rota-rod test from 6 h to 48 h, regardless of whether the 5, 10 or 15 rpm speed load was used (Figure 1C). These results showed that pre-treatment with GL had neuroprotective effects on the

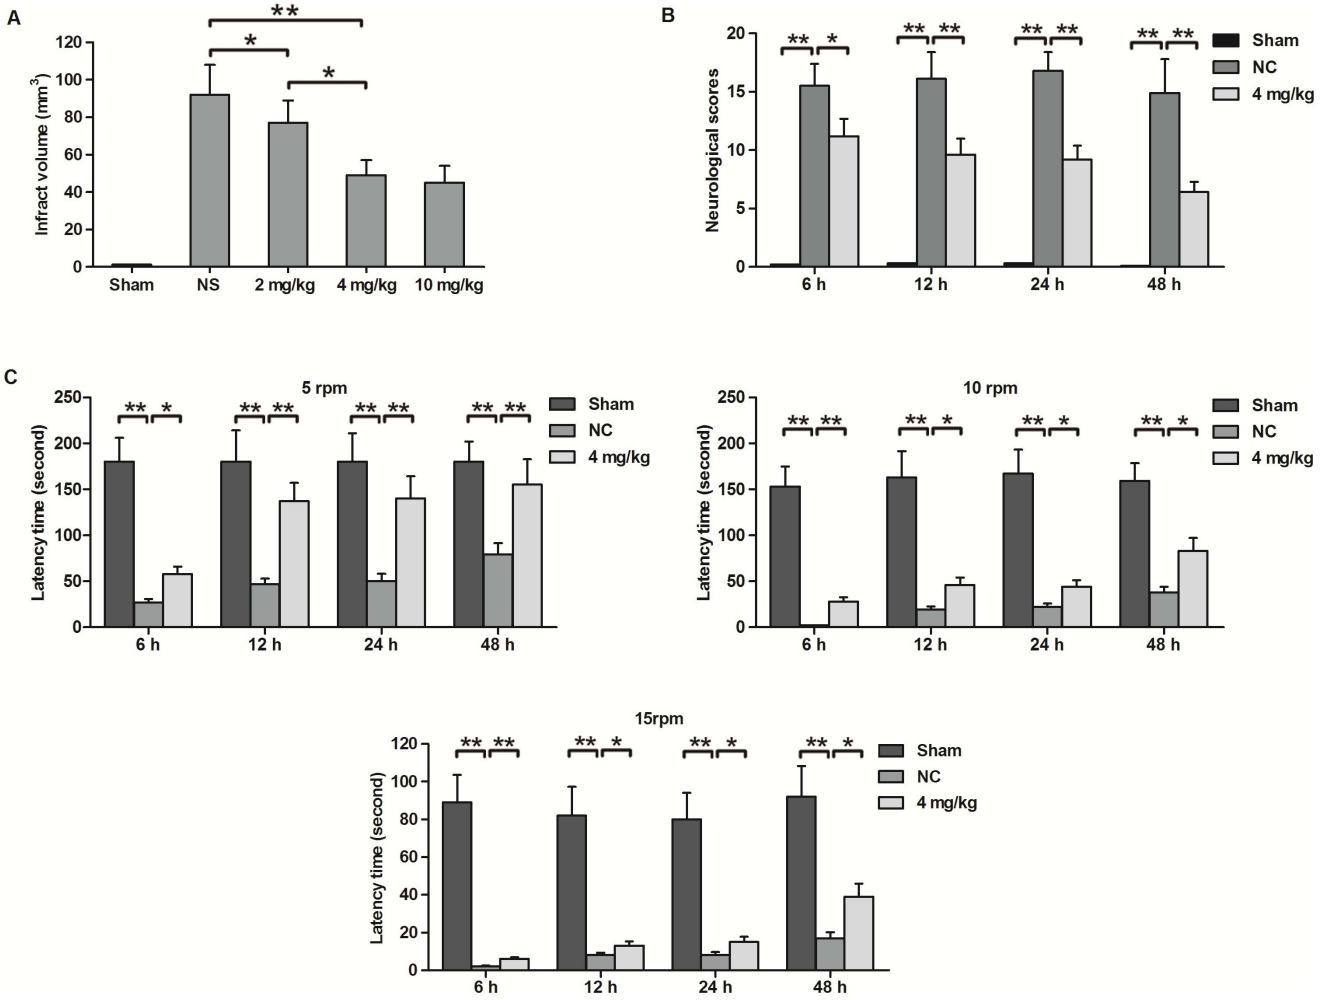

Figure 1. The neuroprotective effect of GL against cerebral I/R injury in rats. A) Cerebral infarction induced by MCA occlusion was evaluated 48 h after reperfusion by TTC staining of brain slices from rats treated with different doses of GL or NS. Sham-operated rats showed no infarction or TTC staining. The infarct volumes were quantified using computerised image analysis. B) Neurological scoring was carried out according to the categories described in the Materials and Methods. C) Neurological deficits in rats after MCA occlusion were examined using the rota-rod test. In the rota-rod test, trials were performed at 3 different speeds, and the time intervals running on the rod were determined for each rat after reperfusion. Values are means±SEM, n = 8 for each group. *P<0.05, **P<0.01 (t test).
doi:10.1371/journal.pone.0089450.g001

post-ischemic brain, which were manifested as improvements in motor impairments and neurological deficits scores.

Inhibition of HMGB1 release by GL in rats that underwent MCAO

We observed that plasma HMGB1 levels rapidly increased starting 6 h after MCAO for 1 h, peaked at 24 h after reperfusion, and then declined slowly (Figure 2A–B). When rats were pre-treated with 4 mg/kg GL, the plasma HMGB1 level was significantly decreased compared with that observed in the NS group at any time during the experimental procedure (Figure 2A–B). At 12 h after MCA occlusion (MCAO)/reperfusion, brain HMGB1 levels in the infarct area declined significantly to below the basal level and reached a minimum value at 24 h after MCAO/reperfusion. Moreover, at each time point from 12 h to 48 h after MCAO/reperfusion, brain HMGB1 levels after treatment with GL were significantly higher than those observed in the NS group (Figure 2C).

Immunofluorescence staining of nuclear HMGB1 was observed in the cerebral cortex in rats from the sham group (Figure 2D). However, the staining almost disappeared in the core of the infarct in the NS group 48 h after reperfusion, and markedly increased HMGB1 staining was observed in the extracellular space. The number of nuclear HMGB1-positive cells significantly increased upon pre-treatment with 4 mg/kg GL, and this was accompanied by a decrease in extracellular HMGB1 staining. These data suggested that increased serum levels of HMGB1 are probably attributable to spill-over from necrotic neural cells during cerebral ischemia and that GL may have a protective effect against MCAO/reperfusion-mediated cell death in neural cells, thereby decreasing the amount of HMGB1 released from the cerebral cortex into the serum.

GL inhibits HMGB1-dependent apoptotic injury

To further demonstrate that the protective effect of GL against brain I/R injury occurs via antagonism of HMGB1 function, we determined the infarct volumes of rat brains under conditions in

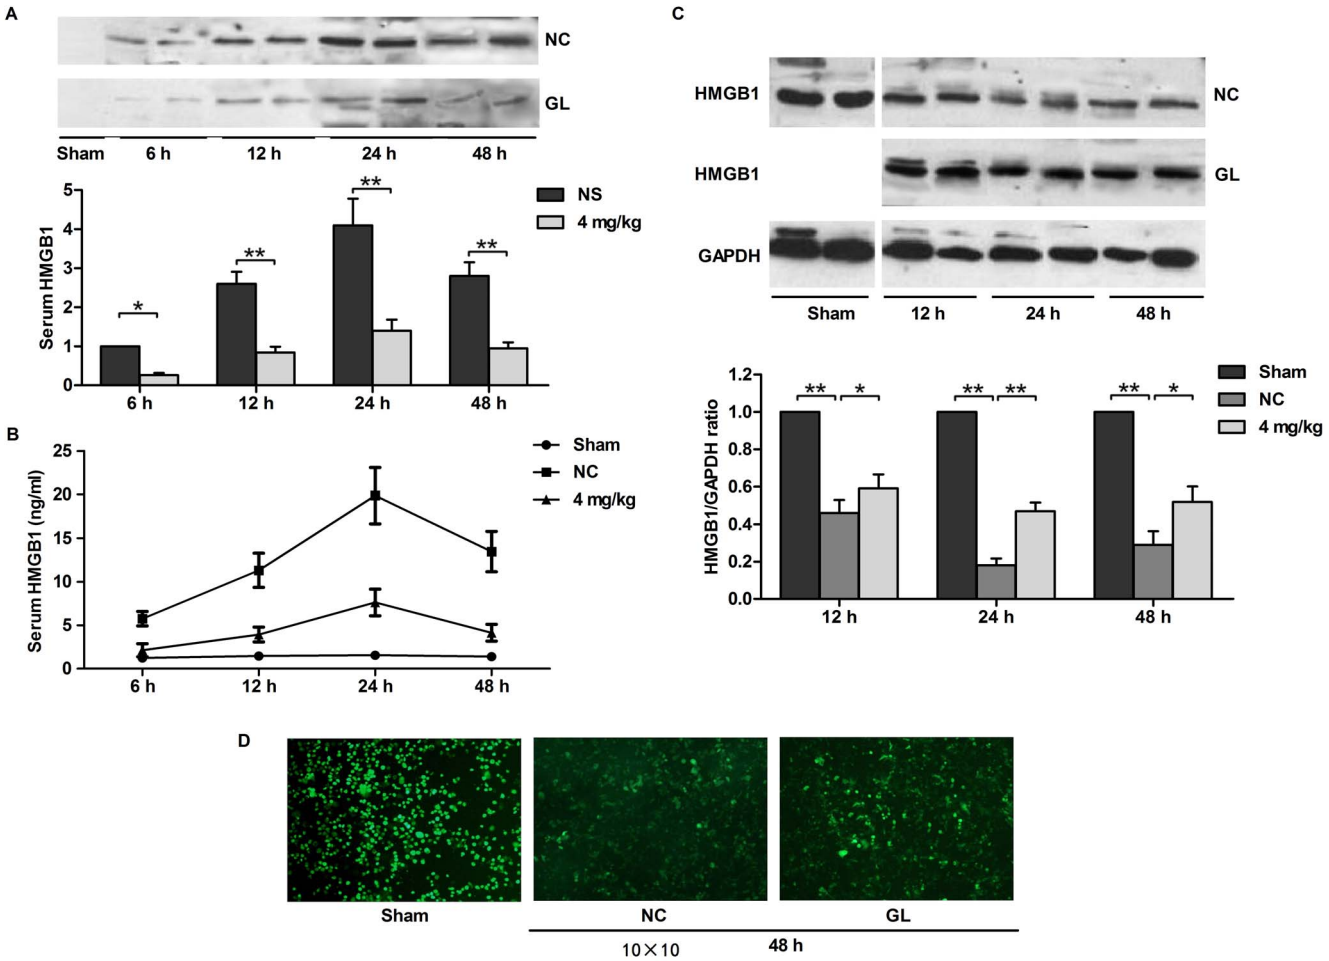

Figure 2. Inhibition of HMGB1 release by GL in the I/R brain. A) The serum HMGB1 concentrations of 4 mg/kg GL-pre-treated rats were determined by immunoblot at the indicated times after 1 h of MCAO. B) Serum HMGB1 concentrations were also determined by ELISA. Values are means±SEM, n = 8. **P<0.01 (t test). C) HMGB1 levels in I/R hemispheres were determined by immunoblot at various times after 1 h of MCAO. GAPDH was used as a loading control. D) Immunofluorescence staining showing different extracellular and intracellular distributions of HMGB1 in the I/R hemispheres after 48 h reperfusion. Values are means±SEM, n = 8 for each group. *P<0.05, **P<0.01 (t test).
doi:10.1371/journal.pone.0089450.g002

which rHMGB1 was included. As shown in Figure 3A, although the infarct volume was significantly decreased in the 4 mg/kg GL group compared with the NS group, co-treatment with 4 mg/kg GL and 100 μg rHMGB1 30 min before ischemia significantly alleviated these changes, resulting in infarct volumes similar those observed in the NS group.

Next, we investigated whether the anti-inflammatory effect of GL can alleviate I/R-induced, HMGB1-dependent apoptosis and whether cytochrome C and caspase 3, the two most important players, are involved in this process. As depicted in Figure 3B, a large number of TUNEL-positive cells was observed in the right cortex of rats subjected to I/R injury, whereas TUNEL positive cells were not detected in the right cortex of sham-operated rats. Upon pre-treatment with 4 mg/kg GL, the number of TUNEL-positive cells was significantly reduced in the right cortex compared with the NS group. Moreover, co-treatment with rHMGB1 increased the number of TUNEL-positive cells, as expected.

In the sham group, under basal conditions, cytochrome C was predominantly expressed in the mitochondrial fraction (Figure 3C). The NS group exhibited a significant decrease in cytochrome C expression in the mitochondrial fraction when compared with the sham group, whereas an increase was observed in the cytosolic fraction. Pre-treatment with GL resulted in a significant increase in cytochrome C expression in the mitochondrial fraction and a decrease in the cytosolic fraction compared with the NS group. However, expression still did not reach the level observed in the sham group. Moreover, co-treatment with rHMGB1 can partly abolish the effect of GL on the subcellular distribution of cytochrome C proteins between the cytosolic and mitochondrial fractions. There was no significant difference in the total expression of cytochrome C protein between each group (Figure 3C). As an executioner caspase, the change in caspase 3 activity was similar to that observed with cytochrome C expression in the cytosolic fraction (Figure 3D). These results demonstrate that the administration of GL significantly alleviates the cerebral cell apoptotic injury caused by I/R through the antagonism of HMGB1 function and that the mechanism involved regulation of cytochrome C release and caspase 3 activation.

GL inhibits HMGB1-dependent inflammatory molecule expression and oxidative stress

The expression of mRNA encoding inflammation- and oxidative stress-related molecules was determined by RT-PCR. As

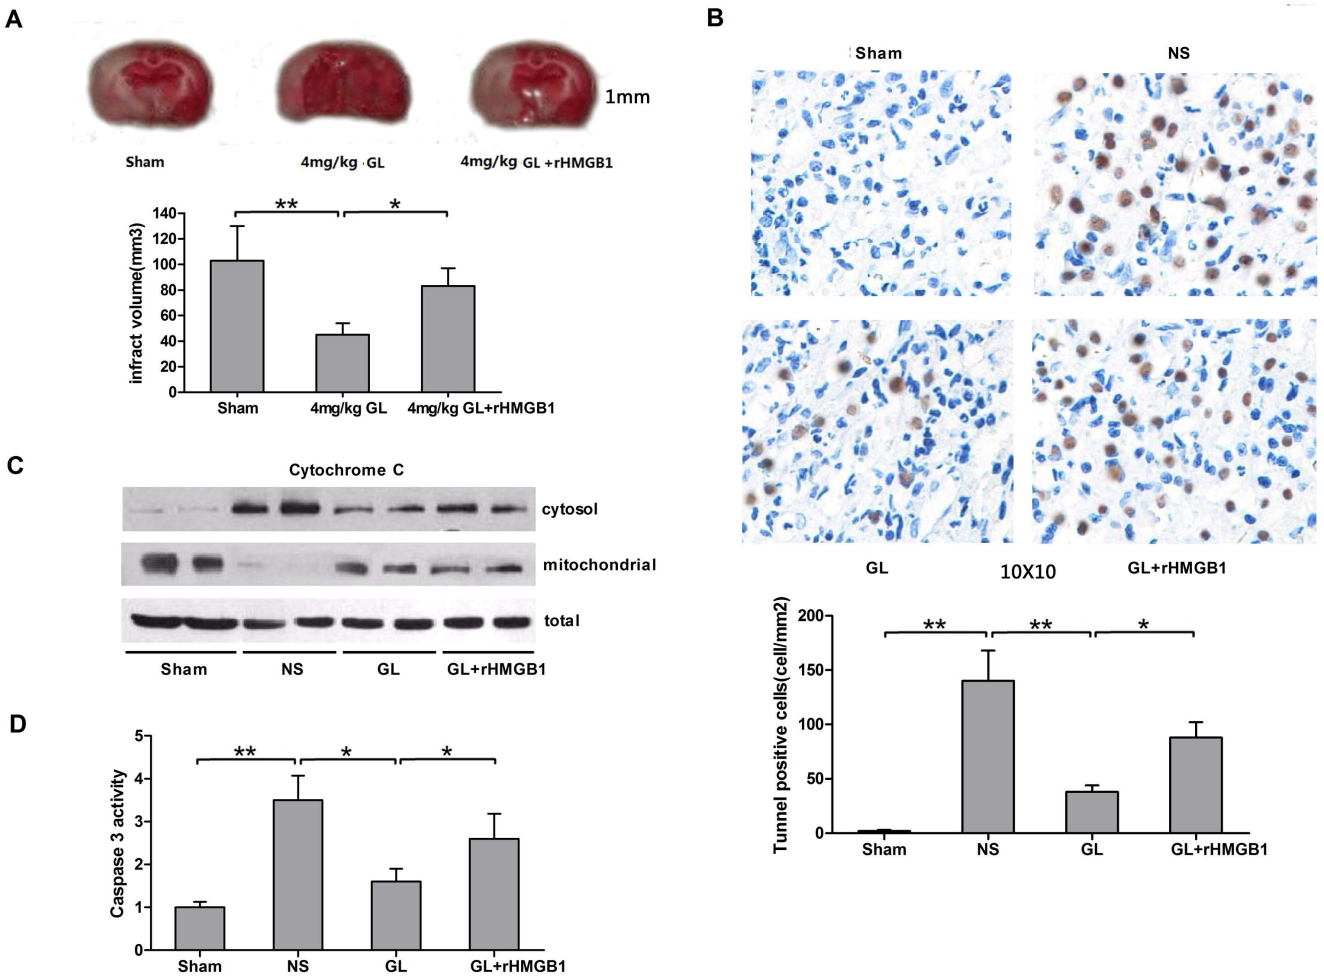

Figure 3. The protective effect of GL on I/R-induced infarct volume and apoptosis injury is HMGB1 dependent. A) Brain infarction induced by right MCA occlusion was evaluated by TTC staining from rats pre-treated with 4 mg/kg GL with or without 100 μg recombinant HMGB1, and the infarct volumes 48 h after reperfusion were quantified using NIH image software. B) Representative photomicrographs show TUNEL staining for apoptotic cells in rat brains at 48 h after reperfusion in the sham, NS, GL and GL+rHMGB1 groups. Effects on the severity of cerebral apoptosis are shown in an average quantitative analysis of the number of TUNEL-positive cells. C) Representative blots showing the effects of GL with or without rHMGB1 treatment on Cytochrome c translocation between the mitochondrial and cytosolic fractions. D) Effects of GL with or without rHMGB1 treatment on caspase-3 activity in areas at the risk zone of cerebral tissues at 48 h after reperfusion. Values are means±SEM, n = 8 for each group. *P<0.05, **P<0.01 (t test).
doi:10.1371/journal.pone.0089450.g003

showed in Figure 4A, MCA occlusion/reperfusion significantly up-regulated the expression of TNF-α, iNOS, IL-1β, COX-2 and IL-6 in the cerebral cortex compared with the non-ischemic side in the sham group. Treatment with GL significantly inhibited the expression of TNF-α, iNOS, IL-1β and IL-6 but had no apparent effect on the expression of COX-2. In contrast, co-treatment with rHMGB1 and GL again enhanced the expression of TNF-α, iNOS, IL-1β and IL-6 compared with the GL-pre-treatment alone group ($P<0.01$). The serum concentrations of TNF-α, iNOS, IL-1β and IL-6 in each group showed a similar trend to that of the mRNA expression levels, as determined by ELISA (Figure 4B). These results indicated that GL can inhibit the I/R-induced expression of HMGB1-dependent inflammation- and oxidative stress-related molecules in rat brains.

In the sham group, little DHE-induced EtBr fluorescence or 3-NT immunoreactivity was observed. The relative fluorescence intensities of superoxide-generating cells and 3-NT–positive cells were significantly increased in the NS-treated I/R hemisphere (Figure 5A–B). When rats were pre-treated with 4 mg/kg GL, the fluorescence intensity caused by superoxide and 3-NT production was significantly reduced compared with the NS group. In contrast, co-treatment with 4 mg/kg GL and 100 μg rHMGB1 enhanced the fluorescence intensity of superoxide and 3-NT production compared with the GL group, though the intensity was still lower than that in the NS group (Figure 5A–B). These histological results were further supported by a biochemical assay for MDA, a lipid peroxidation product. Pre-treatment with 4 mg/kg GL significantly decreased the level of MDA, compared with the NS group, while co-treatment with 100 μg rHMGB1 again increased the level of MDA, though this was still lower than that in the NS group (Figure 5C).

GL modulates P38 and P-JNK but not p-ERK signalling

The mitochondrial-dependent apoptosis pathway is tightly regulated by the mitogen_activated protein (MAP) kinase family, and among these, JNK, ERK1/2, and p38 have been demonstrated to be activated during I/R injury [28,29]. To study whether GL can modulate MAP kinase activity, we analysed these

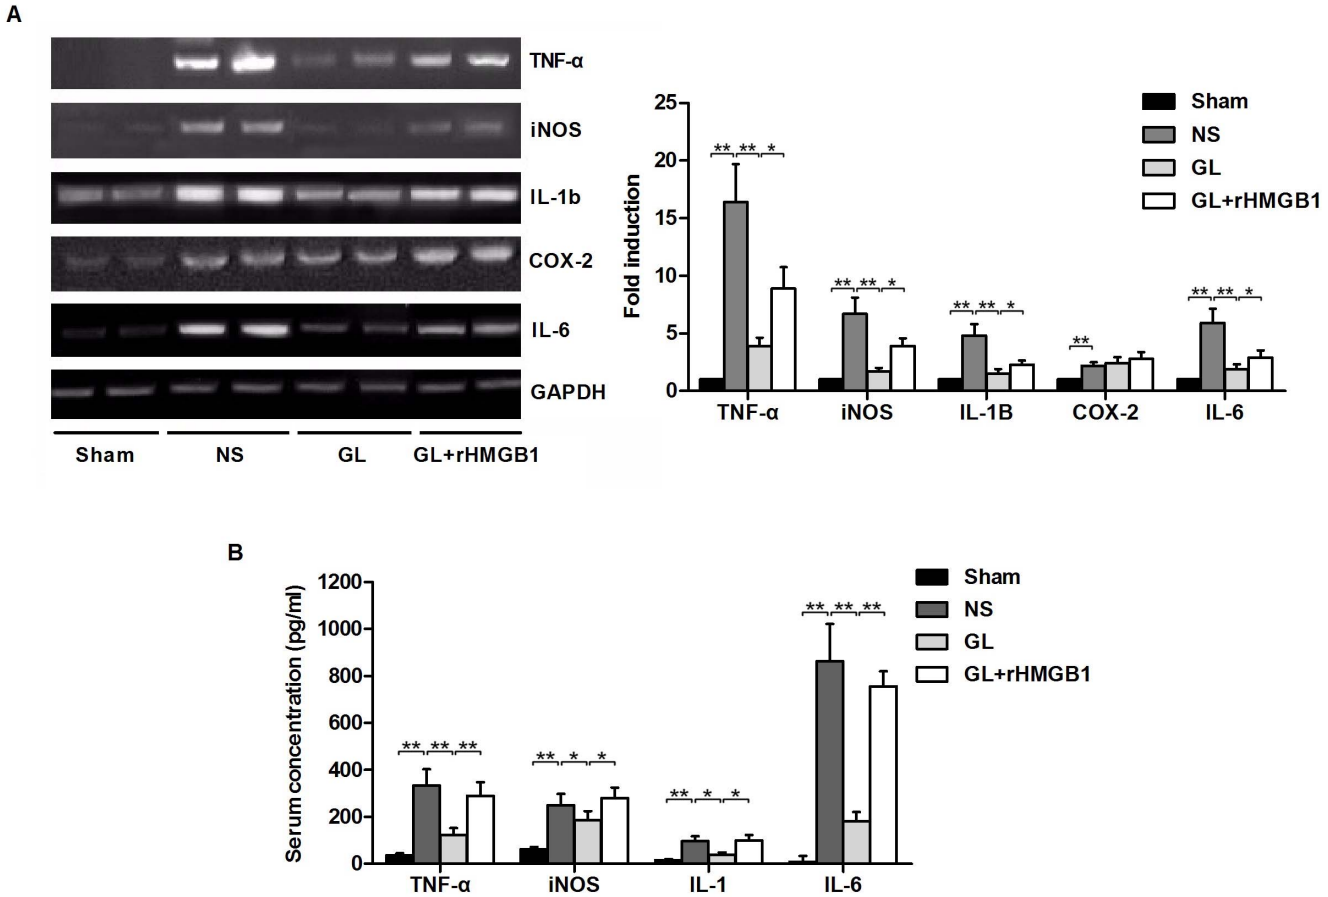

Figure 4. Expression of inflammation- and oxidative stress-related molecules in the brain and serum of MCA-occluded rats at 48 h after reperfusion. A) Representative blots showing the effects of GL with or without rHMGB1 treatment on mRNA expression levels of pro-inflammatory and oxidative stress markers: TNF-α, iNOS, IL-1β, COX-2 and IL-6. GAPDH was used as a loading control. The bar graph showing semi-quantitative densitometric analysis summarises the fold change of TNF-α, iNOS, IL-1β, COX-2 and IL-6 expression in each group. B) Serum concentrations of TNF-α, iNOS, IL-1β, COX-2 and IL-6 at 48 h after I/R in each groups are determined. Values are means±SEM, n = 8 for each group. *P<0.05, **P<0.01 (t test).
doi:10.1371/journal.pone.0089450.g004

MAP kinases by immunoblotting. As shown in Figure 6, I/R induced phosphorylation of JNK, ERK, and p38 in isolated rat brain cerebral cortex. In GL-pre-treated rats, the phosphorylation levels of p38 and p-JNK were decreased compared with the NS-treated group, whereas p-ERK1/2 was not affected. Co-treatment with rHMGB1 enhanced the phosphorylation of p38 and JNK compared with the GL group, but the levels were still lower than those observed in the NS group. Pre-treatment with GL alone or with rHMGB1 did not affect the total levels of the JNK, ERK1/2, and p38 proteins. These results demonstrated that GL can modulate the p38 and JNK signalling pathways, but not the ERK signalling pathway, in the brains of MCA-occluded rats and that this effect is HMGB1 dependent.

Discussion

Traditional Chinese medicine has become increasingly important in the treatment of cardiovascular ischemia/reperfusion injury. GL is a natural anti-inflammatory compound that is commonly used in Japan to treat patients with chronic hepatitis [14–17]. In the present study, we demonstrated that intravenous pre-treatment with a wide range of concentrations of GL, from 2 mg/kg to 10 mg/kg, reduced cerebral infarct volumes and ameliorated the neurological deficits of rat cerebral I/R injury. The use of a medium concentration of 4 mg/kg yielded considerable improvements, similar to those found at the high concentration of 10 mg/kg GL. Furthermore, this neuroprotective effect was accompanied by a reduction in the release of HMGB1 into the extracellular space and in the related inflammatory factors TNF-α, iNOS, IL-1β, and IL-6, both in the brain and serum of rats (Figure 2 and 4). Using this dose, no significant toxicities were observed in the effects investigated, including changes in the baseline hemodynamic values, cardiac electrophysiology, and in histopathological analysis of vital organs including liver, spleen, lung, kidney, and brain (data not shown).

HMGB1 is a nonhistone DNA-binding protein that possesses two HMG boxes that are DNA binding domains [30]. As a chromosomal protein, it has been implicated in diverse intracellular functions including stabilising nucleosomal structure and facilitating of gene transcription [31]. Moreover, HMGB1 is massively released extracellularly and plays a cytokine-like function in the post-ischemic brain [26,32]. HMGB1 is actively secreted by macrophages and monocytes or released by necrotic cells into the extracellular milieu, where it might be involved in triggering inflammation [33–36]. The present study demonstrated that the predominantly nuclear HMGB1 staining of neurons in rats from the sham group weakened and disappeared during

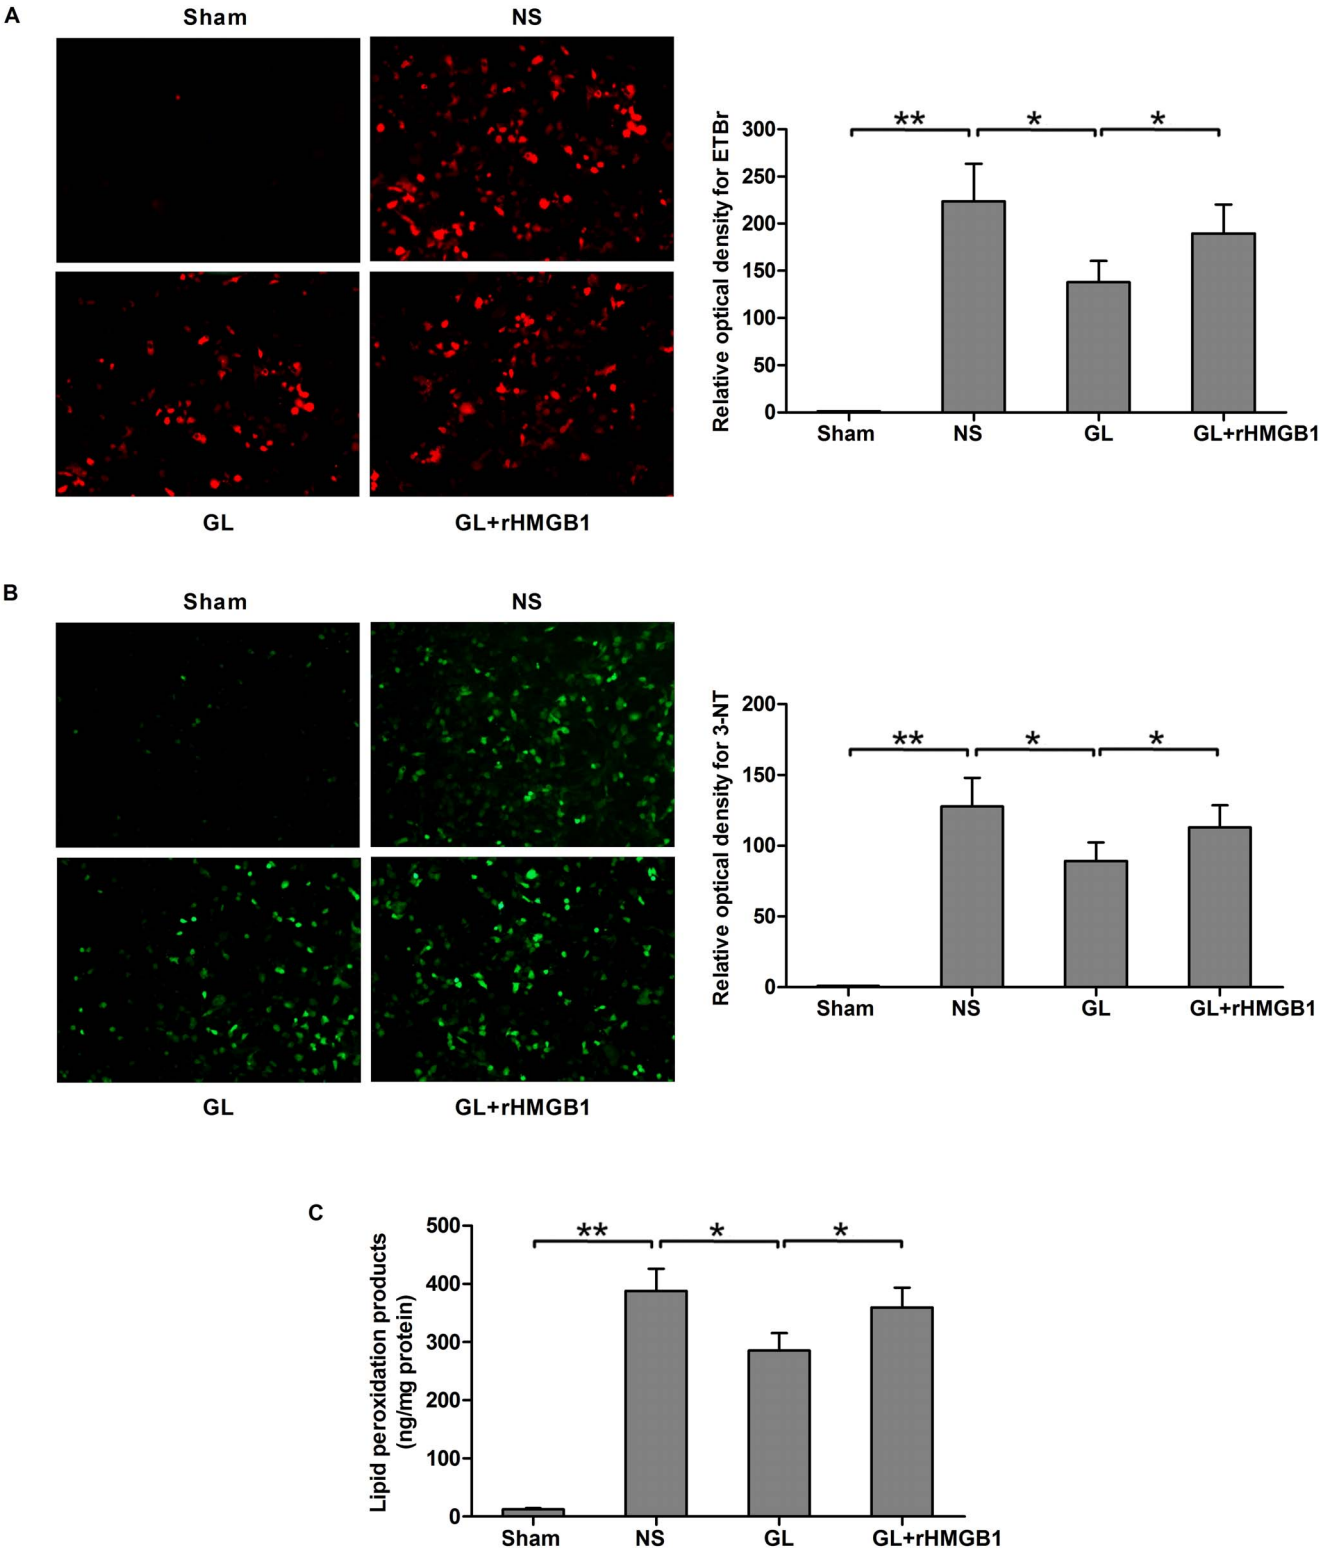

Figure 5. The antioxidant effects of GL are HMGB1 dependent. A) Fluorescent images after incubation with DHE showing superoxide levels in the I/R brain (red). Quantitative measurements of the fluorescence intensity indicated a significant change in the 4 mg/kg GL-treated group with or without rHMGB1, compared with the saline-treated I/R (NS) group. B) Representative photomicrographs showing 3-NT formation in the ischemic brain (green). doi:10.1371/journal.pone.0089450.g006

cerebral ischemia (Figure 2D). Thus, release from necrotic neural cells is the most likely source of elevated HMGB1 concentrations in the serum, which were further determined by immunoblot analysis in rats subjected to focal cerebral ischemia. A recent report of elevated serum concentrations of HMGB1 in stroke patients confirmed our findings [37]. Antagonising the pro-inflammatory function or blocking the expression of HMGB1 by a neutralising antibody [11,12], HMGB1 box A [11], or a short hairpin RNA [10,13] ameliorated brain damage. In particular, the expression of TNF-α, iNOS and IL-1β, which were all up-regulated in the post-ischemic brain, was reduced when HMGB1 was inhibited [10,11], consistent with our results. HMGB1 has been reported to stimulate the production of IL-1, TNF-α, IL-6, and IL-8 and to induce iNOS expression [38,39]. In the present study, we demonstrated that the ischemia-induced up-regulation of iNOS, IL-1β, IL-6 and TNF-α was inhibited by treatment with GL. Co-treatment with rHMGB1 can partially reverse this effect (Figure 4). The induction of iNOS and TNF-α following an ischemic insult was reported to occur mainly in microglia. Thus, it is likely that HMGB1 activates microglia in the brain, leading to the up-regulation of iNOS and TNF-α expression. In fact, the induction of iNOS and TNF-α has been reported to be involved in the inflammatory response and the disruption of the blood-brain barrier, leading to the aggravation of brain infarction [40,41]. The regulation of any one of these factors has been postulated to reduce ischemic injury. Therefore, it is reasonable that GL, which has the ability to substantially reduce the expression of pro-inflammatory factors, exerted profound therapeutic effects on brain infarction.

In this study, pre-treatment with GL alleviated apoptosis injury resulting from cerebral I/R, and this was at least partly due to the inhibition of cytochrome C release and caspase 3 activity. Similarly, GL exhibited an anti-apoptotic effect by preventing HMGB1-induced cytochrome C release and caspase 3 activation in vitro in Huh-BAT cells [42]. Though the anti-apoptotic effect of GL has been linked with HMGB1 inhibition and caspase-dependent cytochrome c release, the question remains how GL regulates caspase-dependent cytochrome c release through the inhibition of HMGB1. The exact answer is not known at the present time, but we speculate that GL may modulate the activity of a particular kinase that contributes to cytochrome c translocation and is involved in I/R-induced HMGB1-dependent apoptosis.

Apoptosis is tightly regulated by the mitogen-activated protein (MAP) kinase family, and the JNK, ERK1/2, and p38 members of this family have been demonstrated to be activated in I/R injury. MAPKs play important roles in transducing signals by phosphorylating intracellular enzymes, transcription factors and cytosolic proteins involved in apoptosis and inflammatory cytokine production. Sustained MAPK activation has been shown to be associated with neuronal cell death/apoptosis following ischemic stroke, and the inhibition of this pathway is neuroprotective. In a Huh-BAT cell model, GL prevented HMGB1_induced cytochrome c release and p38 activation but had no effect on phospho_JNK and ERK1/2 [42]. In I/R-induced myocardial injury of rat heart, treatment with HMGB1 box A significantly reduced ERK1/2 and JNK phosphorylation, but did not affect the level of phospho-p38 [43]. However, in another similar study, treatment with GL significantly decreased JNK phosphorylation, but did not affect the level of phospho-p38 and ERK1/2[21]. Interestingly, in our studies, GL could modulate the p38 and JNK signalling pathways, but did not affect the ERK signalling pathway in the brains of MCA-occluded rats, and rHMGB1 could reverse this effect (Figure 6). This ambiguity regarding which single class of MAPK can be modulated by GL appears to primarily depend on the cell and tissue types used and differences in MAPK levels in vivo and in vitro.

In conclusion, our results demonstrated that pre-treatment with GL blocked and inhibited the extracellular cytokine activity of HMGB1 and explored the protective effect on I/R-induced apoptosis through the blockage of the JNK and p38-mediated pathways in rats in vivo. These data suggest a new therapeutic possibility for the treatment of ischemic stroke with GL. Considering the biological differences between species that may influence drug adsorption, metabolism, distribution, and toxicity in rats and humans, it is not clear whether GL has similar protective effects in humans. Hence, future research should be performed to evaluate the beneficial protective effect of GL in

clinical settings with humans, as this might ultimately lead to a new therapeutic strategy for ischemic stroke.

Effect of glycyrrhizin on traumatic brain injury in rats and its mechanism

*Gu Xiangjin, Xu Jin, Ma Banyou, Chen Gong, Gu Peiyuan, Wei Dong, Hu Weixing**

【**Abstract**】**Objective:** To investigate the neuroprotective effects of glycyrrhizin (Gly) as well as its effect on expression of high-mobility group box 1 (HMGB1) in rats after traumatic brain injury (TBI).

Methods: Male Sprague-Dawley rats were randomly divided into three groups: sham group, TBI group, and TBI+Gly group (*n*=36 per group). Rat TBI model was made by using the modified Feeney's method. In TBI+Gly group, Gly was administered intravenously at a dosage of 10 mg/kg 30 min after TBI. At 24 h after TBI, motor function and brain water content were evaluated. Meanwhile, HMGB1/HMGB1 receptors including toll-like receptor 4 (TLR4) and receptor for advanced glycation end products (RAGE)/nuclear factor-κB(NF-κB) signaling pathway and inflammatory cytokines in the injured brain tissues were detected using quantitative real-time polymerase chain reaction, western blot, electrophoretic mobility shift assay and enzyme-linked immunosorbent assay. Furthermore, HMGB1, RAGE and TLR4 immunohistochemistry and apoptosis were analyzed.

Results: Beam walking performance impairment and brain edema were significantly reduced in TBI+Gly group compared with TBI group; meanwhile, the over-expressions of HMGB1/HMGB1 receptors (TLR4 and RAGE)/NF-κB DNA-binding activity and inflammatory cytokines were inhibited. The percentages of HMGB1, RAGE and TLR4-positive cells and apoptotic cells were respectively 58.37%±5.06%, 54.15%±4.65%, 65.50%±4.83%, 52.02%±4.63% in TBI group and 39.99%±4.99%, 34.87%±5.02%, 43.33%±4.54%, 37.84%±5.16% in TBI+Gly group (all $P<0.01$ compared with TBI group).

Conclusion: Gly can reduce secondary brain injury and improve outcomes in rat following TBI by down-regulation of HMGB1/HMGB1 receptors (TLR4 and RAGE)/NF-κB-mediated inflammatory responses in the injured rat brain.

Chin J Traumatol 2014;17(1):1-7

Traumatic brain injury (TBI) is one of the major causes of mortality and neurological disability. TBI has been classified into primary injury and secondary injury, and the latter plays a crucial role in the clinical outcome of patients with TBI.[1] Posttraumatic inflammation can aggravate secondary brain injury and result in neurological deterioration.[2] Therefore, reduce of inflammation after TBI contributes to better prognosis of TBI patients.

High-mobility group box 1 (HMGB1) is a kind of non-histone protein that widely exists in the eukaryotic cells. After injury, it is released outside cells and becomes an important mediator of inflammation.[3] The extracellular HMGB1 can bind to cell surface receptors like receptor for advanced glycation end products (RAGE) and toll-like receptor 4 (TLR4).[4,5] These combinations activate nuclear factor-κB (NF-κB) signaling way[5,6] and produce many inflammatory cytokines such as tumor necrosis factor-α (TNF-α), interleukin-1β (IL-1β), and interleukin-6 (IL-6),[6,7] resulting in inflammatory responses. It has been reported that the levels of HMGB1 in cerebrospinal fluid and plasma are increased in patients after TBI, and the increased levels are associated with poor outcomes of patients.[8,9] HMGB1 may implicate a critical role in promoting inflammation and aggravating damage after TBI.

Glycyrrhizin (Gly) is a natural anti-inflammatory triterpene that largely exists in the roots and rhizomes of licorice. Recently, Gly has been found to be able to bind to HMGB1 and inhibit cytokine-like activities of HMGB1.[10] Here we investigate the neuroprotective effects of Gly against TBI in a rat model and its preliminary mechanism.

METHODS

Drugs and reagents

The main drugs and reagents included Gly (Minophagen Pharmaceutical Co, Japan), Trizol reagent (15596-026, Invitrogen Life Technologies, USA), the first chain of cDNA synthesis kit (K1622, Thermo Fisher Scientific Inc, USA), Taq DNA polymerase and EMSA Kit (EP0405 and 20148, both Thermo Fisher Scientific Inc, USA), oligonucleotide probe (5-agttgaggggactttcccaggc-3) (GS056B, Beyotime Institute of Biotechnology, China), anti-HMGB1 antibody (ab18256, Abcam, Cambridge, USA), anti-RAGE antibody and anti-TLR4 antibody (bs-0177R and bs-1021R, both Biosynthesis Biotechnology, China), rat IL-1β ELISA Kit (ERC007, Neobioscience Technology Company, China), as well as EliVision plus Kit and DAB Kit (Kit-9902 and DAB-1031, Maixin-Bio, China). Other main reagents were from Nanjing KeyGen Biotech, China.

Subjects and groups

Altogether 108 male Sprague-Dawley rats weighting 250-300 g were provided by the experimental animal center of Nanjing Medical University, China. All the programs followed the guides for care and use of experimental animals. Rats were placed on a 12-hour light-dark cycle with free access to food and water. Rats were randomly divided into three groups: sham group, TBI group and TBI+Gly group (n=36 for each). Rat model of TBI was established according to the modified Feeney's free weight-drop method.[11] Sham rats received right parietal craniotomy alone without head trauma. Rats in the other two groups suffered TBI; 30 min later TBI+Gly group were intravenously administered Gly at the dose of 10 mg/kg, while sham and TBI groups received equal volume of 0.9% saline solution.

At 24 h after operative procedure, randomly 6 rats in each group received beam walking test.[12] Then all the 108 rats were sacrificed and each group was further divided into 6 subgroups (n=6 for each) for tissue assays including brain water content test, quantitative real-time polymerase chain reaction (RT-PCR), western blot (WB), electrophoretic mobility shift assay (EMSA), enzyme-linked immunosorbent assay (ELISA) and immunohistochemistry and apoptosis detection.

For RT-PCR, WB, EMSA and ELISA, the tissue specimens were harvested within 3 mm area to the injured cortex and immediately stored in liquid nitrogen until detection. For immunohistochemistry and apoptosis detection, the rats were transcardially perfused with 4°C 0.1 mol/L phosphate buffered saline (PBS), followed by 4% buffered formaldehyde combined with PBS. Subsequently brains were removed, soaked with 4% formaldehyde and then embedded in paraffin.

Beam walking test for evaluation of motor function

Under the distraction of bright light and loud white noise, rats escaped along a narrow wooden beam (2.5 cm wide and 120 cm long) to enter a darkened goal box. A score of 7 was given when animals traversed the beam with 2 or less foot slips; 6 was given with less than 50% foot slips; 5 was given for more than 50% but less than 100% foot slips; 4 was given for 100% foot slips; 3 was given for traversal with the affected limb extended and not reaching the surface of the beam; 2 was given when the animal was able to balance on the beam but not traverse it; and 1 was given when the animal could not balance on the beam.[12]

Measurement of water content in brain tissue

After the rats were killed, brains were rapidly harvested and cut through midline. Both cerebral hemispheres (injured and uninjured) were immediately weighed to gain the wet weight, and then placed in an oven at 100°C for 72 h to obtain dry weight. The brain water content was calculated as: (wet weight-dry weight)/wet weight×100%.[13]

RT-PCR detection of HMGB1, RAGE and TLR4 mRNA expression

Total cellular RNA was isolated from brain samples using Trizol reagents. RNA was transcribed to cDNA using the first chain of cDNA synthesis kit and oligo dT primers (Nanjing Genscript Biotechnology, China). The forward and reverse primers were as follows: 5'-ATGGGCAAAGGAGATCCTA-3' and 5'-ATTCATCATCATCATCTTCT-3' for HMGB1 (646 bp), 5'-AGTCCAACTACCGAGTCCGA-3' and 5'-

CAACCAACAGCTGAATGCCC-3' for RAGE (396 bp), 5'-TTGCCTTCATTACAGGGACTT-3' and 5'-CAGAGCGGCTACTCAGAAACT-3' for TLR4 (179 bp), as well as 5'- GCCATGTACGTAGCCATCCA-3' and 5'-GAACCGCTCATTGCCGATAG-3' for β-actin (375 bp). The reaction system was 50 μl. PCR products were detected by 1.5% agarose gel electrophoresis and visualized by the gel imaging system (SynGene G: BOX Chemi XR5, UK). The intensity of every band was quantified using Bandscan 4.3 software, and the ratio of every gene product to β-actin product was considered as the expression of every gene.

WB detection of protein expression of HMGB1, TLR4 and RAGE

Total protein was extracted from brain tissue samples and protein concentration was assayed with Bradford method. Samples (50 μg per lane) were subjected to electrophoresis on 10% SDS-polyacrylamide gels and then transferred onto nitrocellulose. The membranes were blocked with 5% skimmed milk for 1.5 h at 37°C then incubated for over night at 4°C in the presence of anti-HMGB1 polyclonal antibody (diluted 1: 500), anti-RAGE polyclonal antibody (diluted 1:200), anti-TLR4 polyclonal antibody (diluted 1:200) and β-actin (diluted 1:200) respectively. Thereafter they were incubated in the appropriate horseradish peroxidase-conjugated secondary antibody (diluted 1:5 000) for 2 h at room temperature. The blotted protein of every band was analyzed using GelPro32 software after enhanced chemiluminescence and later exposed to X-ray film. The ratio of every protein to β-actin product was considered as the relative strength of expression of every protein.

EMSA detection of NF-κB binding activity

Nuclear protein was extracted from brain tissue samples and protein concentration was determined using BCA kit. According to the LightShift® Chemiluminescent EMSA Kit instructions, 20 μl of nuclear protein (20 μg) was incubated for 20 min at room temperature after adding 1 μl of oligonucleotide probe. The mixture was resolved by electrophoresis on 6% nondenaturing polyacrylamide gel and transferred to membrane, which was then incubated using a UV crosslinker and reacted with Streptavidin-HRP conjugate. Shifted bands after imaging were analyzed using GelPro32 software.

ELISA detection of TNF-α, IL-1β, IL-6

According to the specific rat ELISA Kit instructions, the concentrations of inflammatory cytokines (TNF-α, IL-1β, IL-6) were determined in brain tissue samples. The ratio of every cytokine concentration to total protein concentration was considered as the level of cytokine in brain tissue.

Observation of localization and expression of HMGB1, TLR4 and RAGE by immunohistochemical staining

Peroxidase labeling method was used to detect immunohistochemical staining. The sections were incubated with anti-HMGB1 polyclonal antibody (diluted 1: 1 000), anti-RAGE polyclonal antibody (diluted 1:200) and anti-TLR4 polyclonal antibody (diluted 1:200) for 2 h at 37°C. The sections were incubated with strengthening agent for 30 min and horseradish peroxidase conjugated secondary antibodies for another 30 min at room temperature. After visualization by DAB kit and hematoxylin stain, the sections were observed under a light microscope (×200). The cells with HMGB1 transferred from nucleus to cytoplasm were considered HMGB1-positive. The average percentages of cells positive for HMGB1, RAGE and TLR4 within 0.5 mm area to the contusion cortex were calculated.

Detection of apoptotic cells by TUNEL staining

TUNEL staining was performed according to the manufacture's protocol for situ apoptosis detection kit. The average percentage of TUNEL-positive cells within 0.5 mm area to contusion cortex was calculated under a light microscope (×200).

Statistical analysis

All data were presented as mean±standard error ($\bar{x}\pm s$). SPSS 18.0 was used for statistical analysis. Data were subjected to one-way analysis of variance (ANOVA) followed by least-significant difference (LSD) post hoc test. Statistical significance was defined as $P<0.05$.

RESULTS

Beam walking test score after TBI

Before operation all the rats underwent training on the wooden beam for 3 days and all of them achieved a normal score of 7. The rats in sham group still kept the score of 7 at 24 h after sham operation. But the rats in TBI group had a score of 2.83±0.75 ($P<0.01$ compared with sham group), and those in TBI+Gly group had a score of 4.67±0.82 ($P<0.01$ compared with TBI group).

Brain water content after TBI

At 24 h after injury, brain water content of injured side was 79.97%±0.82% in sham group, 82.94%±0.65% in TBI group (*P*<0.01 compared with sham group), and 80.97%±0.49% in TBI+Gly group (*P*<0.01 compared with TBI group). Brain water contents of uninjured sides were 80.10%±0.69%, 80.38%±0.85% and 80.16%±0.72% for each group, which showed no statistically significant differences.

HMGB1, TLR4 and RAGE expression, NF-κB binding activity and inflammatory cytokines in injured brain tissue after TBI

Compared with sham group, in TBI group the mRNA and protein expression of HMGB1, TLR4 and RAGE around traumatic area were at a much higher level, NF-κB binding activity was significantly up-regulated, and productions of IL-1β, TNF-α and IL-6 were increased (all *P*<0.01). In TBI+Gly group compared with TBI group, the mRNA and protein expression of HMGB1, TLR4 and RAGE around trauma area were expressed at a much lower level, NF-κB binding activity was significantly down-regulated, and productions of IL-1β, TNF-α as well as IL-6 were decreased (all *P*< 0.05, Figures 1-4).

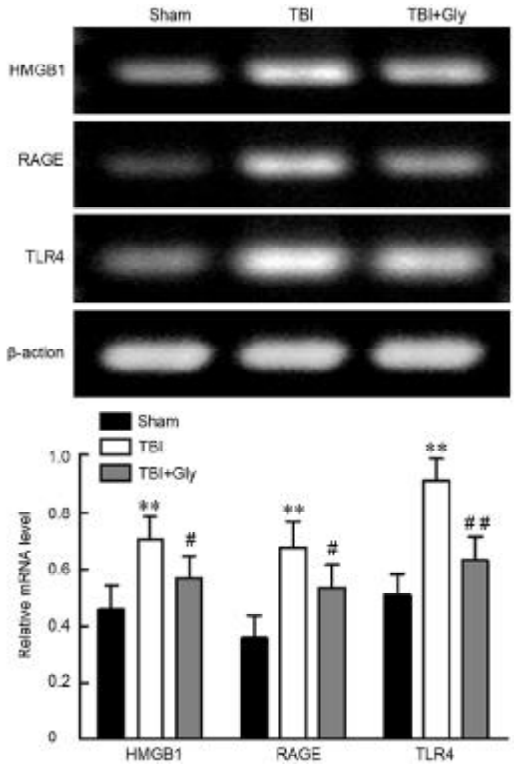

Figure 1. mRNA expression of HMGB1, RAGE and TLR4 by RT-PCR. ***P*<0.01 versus sham group, #*P*<0.05, ##*P*<0.01 versus TBI group.

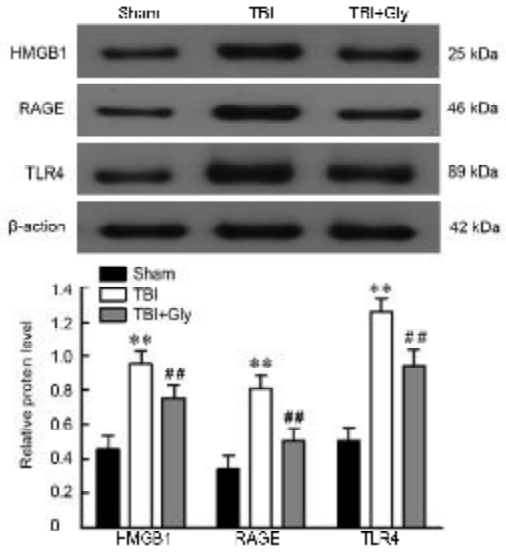

Figure 2. The relevant mRNA and protein expression of HMGB1, RAGE and TLR4. ***P*<0.01 versus sham group, ##*P*<0.01 versus TBI group.

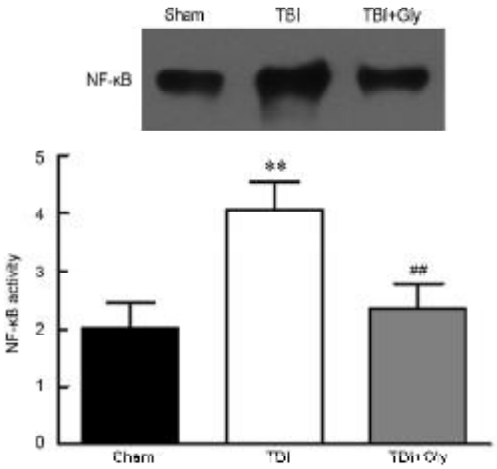

Figure 3. EMSA band and densitometric analysis of NF-κB binding activity. ***P*<0.01 versus sham group, ##*P*<0.01 versus TBI group.

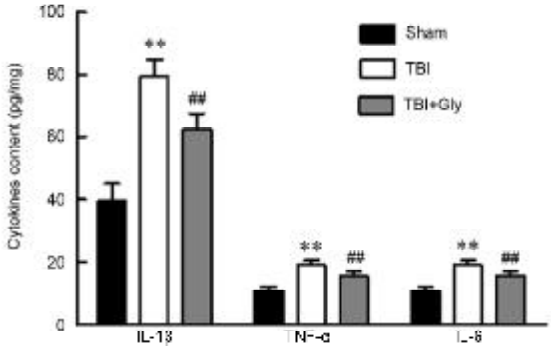

Figure 4. The levels of IL-1β, TNF-α and IL-6 measured by ELISA. ***P*<0.01 versus sham group, ##*P*<0.01 versus TBI group.

HMGB1, RAGE and TLR4-positive cells, apoptotic cells around cortical contusion after TBI

The percentages of HMGB1, RAGE and TLR4-positive cells and apoptotic cells were respectively 7.98%±1.44%, 5.60%±1.12%, 7.60%±1.29%, 8.19%±1.46% in sham group; 58.37%±5.06%, 54.15%±4.65%, 65.50%±4.83%, 52.02%±4.63% in TBI group (all P<0.01 compared with sham group); 39.99%±4.99%, 34.87%±5.02%, 43.33%±4.54%, 37.84%±5.16% in TBI+Gly group (all P<0.01 compared with TBI group, Figure 5).

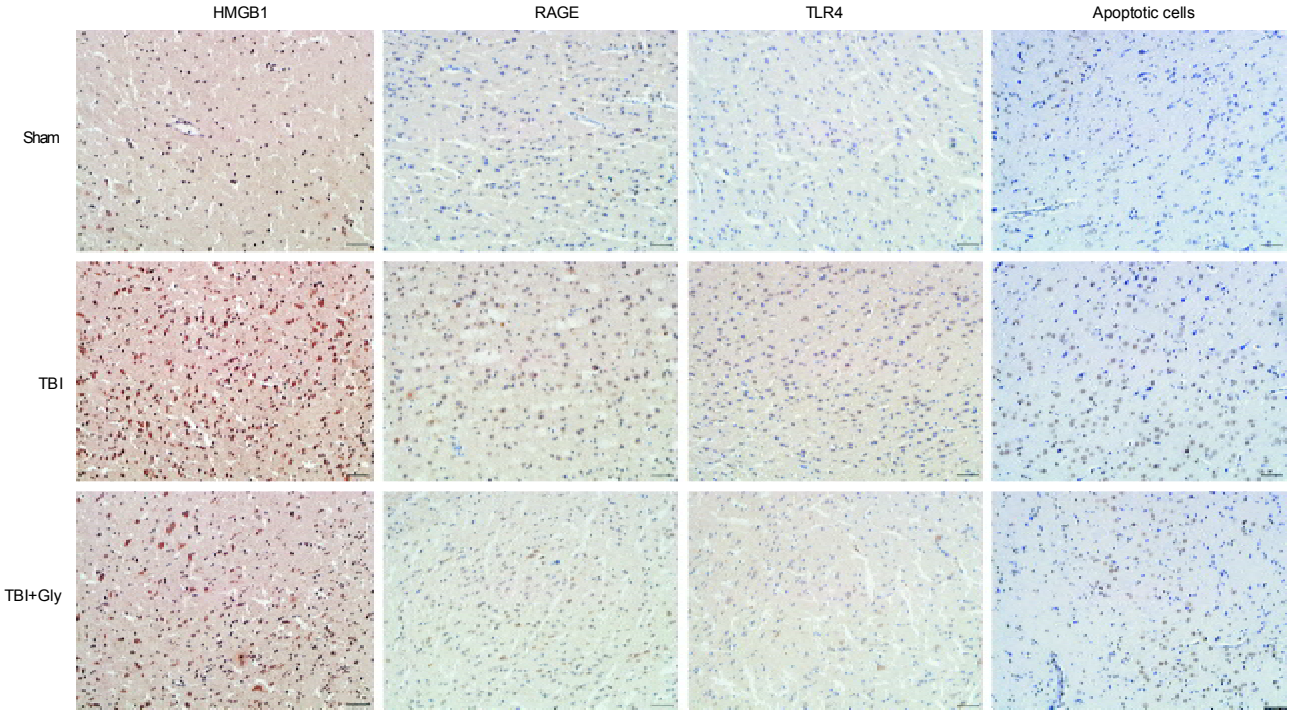

Figure 5. Immunohistochemistry staining showed that HMGB1 mainly distributed in the cell nucleus; few RAGE and TLR4-positive cells were observed in sham group. In TBI group, HMGB1 transferred from nucleus to cytoplasm and mostly redistributed in the cytoplasm; RAGE and TLR4-positive cells were obviously increased. In TBI+Gly group, HMGB1 cytoplasm expression reduced; RAGE and TLR4 positive cells were significantly decreased. TUNEL staining showed that there were few apoptotic cells in sham group. Lots of TUNEL apoptotic cells were showed in TBI group, comparatively less in TBI+Gly group. Scale bar=50 μm.

DISCUSSION

There is mass of evidence to suggest that inflammation plays a vital role in the pathophysiology of TBI. TBI initiates the inflammatory responses by blood brain barrier disruption, brain edema and inflammatory cell infiltration.[14] At the present time, there is no treatment with significant effect clinically. Therefore, exploration of new pharmacologic therapies that target the inflammatory process is necessary for TBI treatment.

Gly is shown to have anti-inflammatory and antiviral effects, and has been used in the treatment of patients with chronic hepatitis.[15] Recently Gly is reported to provide neuroprotective effects on cerebral ischemia[16], intracerebral hemorrhage[17] and ischemic spinal cord injury[18].

In the present experiment, we demonstrate that Gly exerts neuroprotective effects in a rat weight-dropping model of TBI. The results indicate that TBI leads to impair of beam walking balance, brain edema and cell apoptosis. Meanwhile, TBI induces inflammatory responses in the brain tissue, characterized by nucleus-cytoplasm translocation of HMGB1, up-regulated expression of HMGB1/HMGB1 receptors (TLR4 and RAGE), enhanced NF-κB activation, and promoted expression of inflammatory cytokines like IL-1β, TNF-α, and IL-6. Moreover, our results show that Gly administration (1) improves beam walking balance, (2) alleviates brain edema, (3) reduces cell apoptosis, (4) suppresses HMGB1 translocation, (5) inhibits mRNA and protein expressions of HMGB1/HMGB1 receptors (TLR4 and RAGE), (6) represses NF-κB DNA binding activity, and (7) decreases inflammatory cytokines expression. All of the effect support the viewpoint that Gly can reduce secondary inflammation to some extent and improve motor function recovery after TBI. And

to our knowledge, it is the first time that Gly is demonstrated to provide neuroprotective effects following TBI.

HMGB1 is a nonhistone nuclear protein with dual function. Intracellular HMGB1 is bound to DNA and plays an important role in transcriptional regulation. Extracellular HMGB1 conducts as a cytokine-like mediator of inflammation.[3] HMGB1 is a late inflammatory mediator in sepsis and is an early inflammatory mediator in ischemic or traumatic injury.[19] It has been reported that plasma level of HMGB1 increased within 30 min after severe trauma.[20] In our experiment, the expression of HMGB1 mRNA and protein also increased significantly and HMGB1 transferred obviously from nucleus to cytoplasm 24 h after TBI. Extracellular HMGB1 could trigger inflammation through its receptors and signaling pathway. Inflammatory cytokines would, in return, promote the secretion of HMGB1. They are able to form a positive feedback, starting and maintaining a cascade of inflammatory responses. HMGB1 might be the key factor to induce inflammation. Okuma et al[21] used anti-HMGB1 monoclonal antibody to treat TBI in rats and found that it can inhibit HMGB1 translocation, protect blood-brain barrier integrity, suppress inflammatory molecule expression, and improve motor function. Therefore, inhibition of HMGB1 secretion or release represents a novel and promising strategy for the therapy of TBI.

Gly has long been known to exhibit glucocorticiod-like anti-inflammatory actions by inhibiting 11 β -hydroxysteroid dehydrogenase.[22] Recently, Gly is shown to bind directly to HMGB1. Mollica et al[10] reported that Y15, F37, A16, V19, R23, and K42 on HMGB1 are important binding sites for Gly. These sites are very close to some of HMGB1 protein kinase C phosphorylation positions claimed by Oh et al[23]. The direct binding between HMGB1 and Gly may block the interaction between HMGB1 and the protein kinase C, inhibiting HMGB1 phosphorylation. Because phosphorylation of HMGB1 is the initial step for HMGB1 secretion[23], Gly may prevent HMGB1 translocation from nucleus to cytoplasm and break positive feedback loop between the HMGB1 and inflammatory cytokines. In this study, we showed that Gly treatment significantly prevented HMGB1 from cytoplasm translocation and inhibited HMGB1 inflammatory signaling pathway. Gly could retrain excessive inflammatory responses and possess strong neuroprotective effects. Honestly, the underlying molecular mechanism and interaction still needs further exploration.

Our study has some limitations. First, we began Gly intervention at 30 min after TBI. However, this is difficult in clinical practice. Fortunately, it has been reported that Gly suppresses infarct formation with an extended therapeutic window as late as 12 h after stroke.[16] In our further study, we will explore more practical and effective time of Gly intervention in rat TBI model. Second, we intravenously used single Gly dose of 10 mg/kg in this study. We will evaluate the effect of multiple Gly therapeutic doses for maximal neuroprotection in rats after TBI; meanwhile, we will detect the side-effects of Gly, such as pseudo-aldosteronism.[24]

In summary, TBI could induce activation of HMGB1/HMGB1 receptors (TLR4 and RAGE)/NF-κB signaling pathway and inflammatory cytokine expression, which would induce and/or aggravate the secondary brain injury. Gly intervention could down-regulate HMGB1/HMGB1 receptors (TLR4 and RAGE)/NF-κB signaling pathway and inflammatory cytokines expression, decrease brain edema, reduce cell apoptosis and probably improve neurological function after TBI. Gly can be expected to become a new drug for TBI treatment through affecting HMGB1.

The accumulation of hydrophobic bile acids results in cholestatic liver injury by increasing oxidative stress, mitochondrial dysfunction, and activation of cell signaling pathways. Licorice root and its constituents have been utilized as antihepatotoxic agents. The purpose of this study was to evaluate the potential modulation by a primary component of licorice root, glycyrrhizin (GL), and its metabolite, 18β-glycyrrhetinic acid (GA), in a hepatocyte model of cholestatic liver injury. Preincubation of fresh rat hepatocyte suspensions with GL or GA reduced glycochenodeoxycholic acid (GCDC)-dependent reactive oxygen species generation, with GA more potent than GL. Interestingly, GL and GA had opposing effects toward GCDC-induced cytotoxicity; GA prevented both necrosis and apoptosis, whereas GL enhanced apoptosis. GCDC promoted activation of caspase 10, caspase 3, and PARP; all were inhibited by GA but not GL. Induction of apoptosis by GCDC was also associated with activation of JNK, which was prevented by GA. Activation of caspase 9 and dissipation of mitochondrial membrane potential were prevented by GA but not GL. In liver mitochondrial studies, GL and GA were both potent inhibitors of the mitochondrial permeability transition, reactive oxygen species generation, and cytochrome *c* release at submicromolar concentrations. Results from this study suggest that GL exhibits proapoptotic properties, whereas GA is a potent inhibitor of bile acid-induced apoptosis and necrosis in a manner consistent with its antioxidative effect.

Cholestatic liver disorders are characterized by impaired bile flow resulting in the retention of bile constituents and hepatocellular damage. Because there are few effective therapies available, the development of cirrhosis and the need for liver transplantation is a frequent outcome in cholestatic children and adults (1). The accumulation of hydrophobic bile acids within the liver is an important factor in the pathogenesis of cholestatic liver disorders (2). Higher concentrations (≥250 μM) of hydrophobic bile acids, such as glycochenodeoxycholic acid (GCDC), promote hepatocyte death by necrosis, and lower concentrations cause apoptosis (3–5). Mechanistic studies have revealed that several factors, including physicochemical properties (6) and death receptor activation (7), account for the pro-apoptotic effects of bile acids. Activation of cell stress signaling pathways, including caspases and mitogen-activated protein kinases (MAPK),[1] are strongly implicated in both the initiation and execution of events culminating in apoptotic cell death. However, the toxicity of bile acids is not uniform; for example, taurochenodeoxycholic acid not only stimulates apoptotic pathways but also activates cell survival proteins, such as phosphatidylinositol 3-phosphate kinase or MAPK extracellular signal-regulated kinase (ERK1/2) (8). Thus, there is a complex interplay between cell death and survival signals in bile acid-induced cytotoxicity that determines ultimate cell fate.

Extensive evidence also supports the involvement of mitochondrial pathways in bile acid-induced hepatocyte toxicity, including induction of the mitochondrial permeability transition (MPT) (9). Upon MPT induction, there is a loss of mitochondrial polarization, onset of mitochondrial swelling, release of soluble proteins such as cytochrome *c* and apoptosis-inducing factor from the intermembrane space, and activation of caspase 9. Furthermore, oxidative stress generated by mitochondria plays a role in bile acid-induced cellular toxicity, as demonstrated in liver mitochondria (10, 11) and rat hepatocytes (12, 13) as well as in *in vivo* studies with whole animals exposed to bile acids (14). Moreover, a variety of diverse antioxidants reduce both oxidative stress and bile acid-induced hepatocyte toxicity (11–15).

Licorice root is an herbal preparation that has been used for decades to reduce liver injury in a number of clinical disorders. In 1977, Suzuki *et al.* (16) reported that the principal triterpene component of licorice root, glycyrrhizin (GL), benefits patients with chronic hepatitis C infection. Derivatives of licorice root have been used in Asia to treat children with biliary atresia (17), a cholestatic liver disease, although no clinical trials have been reported. Increasing evidence supports the hypothesis that GL, or its hydrolyzed metabolite 18β-glycyrretinic acid (GA), protects against several models of oxidant-mediated tox-

icity, including exposure to CCl_4 (18), *t*-butyl hydroperoxide (19), and ischemia-reperfusion injury (20), with GA generally exhibiting greater hepatic protection than GL. Although several hypotheses have been offered to account for the hepatoprotective effects of GL and GA, the effects of these compounds on molecular and biochemical pathways of cell injury have not been well characterized. Therefore, the purpose of this study was to examine the effects of GA and GL on cell pathways of bile acid-induced cytotoxicity in both freshly isolated rat hepatocyte suspensions and purified liver mitochondrial fractions.

EXPERIMENTAL PROCEDURES

Materials—Sodium glycochenodeoxycholate, lactate dehydrogenase kits, ammonium glycyrrhizin, and 18β-glycyrrhetinic acid were obtained from Sigma. Cyclosporin A (CsA) was purchased from Alexis Biochemicals (San Diego, CA). 2′,7′-Dichlorofluorescin diacetate (DCF-DA) and bovine serum albumin (fraction V) were from Eastman Kodak Co. and Calbiochem, respectively. The fluorescent probe JC-1 was obtained from Molecular Probes (Eugene, OR). Primary antibodies against caspase 3, cleaved caspase 9, caspase 10, native and cleaved PARP, phosphorylated and unphosphorylated p38 MAPK, and phosphorylated and unphosphorylated stress-activated protein kinase/c-Jun N-terminal kinase (SAPK/JNK) were purchased from Cell Signaling Technology (Beverley, MA). All other chemicals were reagent grade or better.

Isolation of Rat Hepatocytes—Hepatocytes were isolated by a recirculating collagenase technique from male Sprague-Dawley rats (175–225 g) (Sasco, Inc., Omaha, NE) maintained on a 12-h light-dark cycle and fed standard laboratory rat chow, as described previously (15). Initial hepatocyte viability measured by trypan blue exclusion was always >94%. Fresh hepatocytes were resuspended in a Krebs-Ringer HEPES (KRH) buffer containing 0.2% bovine serum albumin (KRH/BSA) to a concentration of $\approx 1 \times 10^6$/ml. This study was approved by the Institutional Animal Care and Use Committee, University of Colorado Health Sciences Center.

Measurement of Reactive Oxygen Species in Rat Hepatocytes—Generation of reactive oxygen species (ROS) was measured spectrofluorometrically using the ROS-detecting probe, 2′,7′-dichlorofluorscein (DCFein), as described previously in detail (21). Briefly, hepatocytes were loaded with DCF-DA for 30 min at 37 °C prior to a 30 min preincubation with graded concentrations of GL or GA. DCF-DA is trapped within cells and deesterified, yielding nonfluorescent dichlorofluoroscin, which is oxidized to the fluorescent DCFein by several ROS. Hepatocytes were exposed to GCDC (0 or 100 μM) for 4 h in a 37 °C shaking water bath at room temperature, and aliquots were removed for analysis of ROS by measuring DCFein fluorescence at 490 nm excitation and 520 nm emission. The results were expressed as fluorescence units/10^6 cells.

Determination of Hepatocyte Apoptosis and Necrosis—Hepatocyte apoptosis was quantitated by determining the percentage of hepatocytes with nuclear morphologic changes of apoptosis (fragmentation and margination of chromatin) detected by fluorescence microscopy of DAPI-stained fixed hepatocytes (13). Necrosis was assessed by the release of lactate dehydrogenase activity from cells and expressed as the percentage of total cellular activity released into the medium (13).

Mitochondrial Depolarization—Flow cytofluorometric analysis was performed to determine the effect of GL and GA upon GCDC-dependent mitochondrial depolarization in hepatocytes, as described previously (12). Briefly, freshly isolated hepatocytes were pretreated with 25 μM GL or 10 μM GA for 30 min and then incubated with 100 μM GCDC for 4 h. Aliquots of cells were removed hourly, loaded with 7.6 μM JC-1 or 3 μM propidium iodide for 15 min at 22 °C in the dark, and washed with KRH buffer at 4 °C prior to flow cytometry on a BD Biosciences FACSCalibur using Flojo software. In actively respiring mitochondria within cells, JC-1 aggregates form, and the intensity of their fluorescence at 590 nm is proportional to the mitochondria $\Delta\psi$ and indicative of a closed MPT pore. Neither GL or GA alone affected JC-1 fluorescence. For each time point and treatment 10,000 cells were analyzed. The fluorescence of JC-1 aggregates was determined only in live cells identified through gating for propidium iodide fluorescence.

SDS-PAGE and Immunoblotting—Total cell lysates were obtained from hepatocytes for immunoblot analysis as follows. Hepatocytes (3×10^6) were pelleted by centrifugation at 2500 rpm for 5 min, resuspended in KRH buffer (no bovine serum albumin), and recentrifuged to obtain a washed cell pellet. Cells were lysed in 1 ml of a buffer containing 62.5 mM Tris-HCl, pH 6.8, 6 M urea, 10% glycerol, 2% SDS, 5% β-mercaptoethanol, and 0.00125% bromphenol blue followed by a 15-s sonication on ice, as described by Shah *et al.* (22). Proteins were separated by SDS-PAGE and transferred onto nitrocellulose membranes, and nonspecific proteins were blocked by a 1-h incubation in fresh 5% nonfat dry milk. The blots were probed against the appropriate primary antibody by an overnight incubation at 4 °C followed by a 1-h incubation with rabbit anti-horseradish peroxidase with biotinylated horseradish peroxidase utilized as a size marker. On selected blots, β-actin (Oncogene Research, Boston, MA) was probed to demonstrate equal protein loading.

Mitochondrial ROS Generation—Fresh rat liver mitochondria were isolated by differential centrifugation through a Percoll gradient as described previously (11). ROS were quantitated spectrofluorimetrically using DCFein (11). Briefly, purified mitochondria were resuspended in a buffer containing 5 mM HEPES, 50 mM KCl, 2 mM KH_2PO_4, 125 mM sucrose, pH 7.4, treated with 1% Chelex 100 (wash buffer), and loaded with 8 μM DCF-DA at 28 °C for 30 min. The loaded mitochondria were washed twice with wash buffer, centrifuged at 10,000 × *g* for 10 min, and finally resuspended in 20 ml of a buffer containing 10 mM MOPS, 100 mM NaCl, 125 mM sucrose, pH 7.4, treated with 1% Chelex 100. Mitochondria were then preincubated with graded concentrations of GL or GA, or Me_2SO solvent vehicle. Solvent alone had no effect on any measurements and was at a concentration of ≤0.1%. Mitochondria were then incubated with GCDC, and aliquots were removed at specified time points for DCFein fluorescence measurements at 490 nm excitation and 520 nm emission. The results were expressed as DCFein fluorescence/mg of mitochondrial protein.

MPT and Cytochrome c Content in Liver Mitochondria—MPT induction was quantitated in purified mitochondria spectrophotometrically at 540 nm as described previously (11). Briefly, hepatic mitochondria were preincubated at 25 °C for 5 min alone or in the presence of GL, GA, or the MPT blocker CsA prior to the addition of 100 μM $CaCl_2$, 5 mM sodium succinate, and 5 μM rotenone. Following this 5-min incubation, the MPT was induced by addition of 100 μM GCDC. Mitochondrial swelling was quantitated by the reduction in absorbance at 540 nm during the 5-min incubation with GCDC. After the MPT experiment, mitochondrial samples were centrifuged at 13,000 × *g* for 30 min at 4 °C to isolate the mitochondrial pellet for immunoblot analysis of cytochrome *c* using anti-mouse cytochrome *c* antibody and anti-mouse horseradish peroxidase secondary antibody (BD Biosciences).

Statistical Analysis—Statistical analysis between groups was conducted by analysis of variance using the Scheffe test or by *t* test for comparing means from two groups. A *p* value of <0.05 was considered significant. Values were expressed as means ± S.E.

RESULTS

GL and GA Reduce GCDC-stimulated ROS Generation—To determine the effect of licorice compounds on bile acid-induced ROS generation, freshly isolated rat hepatocyte suspensions were incubated for 4 h with 100 μM GCDC, and DCF fluorescence was measured. GCDC increased DCF fluorescence linearly in a time-dependent manner when compared with control hepatocytes (35.8 ± 1.5 *versus* 9.7 ± 0.9 fluorescence units/10^6 cells at 4 h) (Fig. 1*a*). Pretreatment with GL decreased ROS generation modestly at all concentrations (0.5–25 μM) (Fig. 1*a*). GA treatment reduced ROS generation to a greater extent, with all concentrations reducing ROS generation by >60% at 4 h (Fig. 1*b*). Concentration-effect relationships of the two compounds after 4 h of incubation with GCDC (Fig. 1*c*) showed that both GA and GL function at low concentrations to reduce bile acid-induced oxidative stress, that maximal effect was achieved at low concentrations, and that GA was superior to GL in this effect.

GL and GA Differentially Regulate GCDC-induced Cytotoxicity—We next determined the effects of the licorice compounds on cell death pathways. Hepatocytes exposed to 100 μM GCDC underwent a time-dependent increase in necrosis, as evident by the percent of lactate dehydrogenase leakage (38.2 ± 2.2% *versus* 15.9 ± 1.3% for control cells at 4 h) (Fig. 2). Pretreatment with GL afforded no protection against cell necrosis (Fig. 2*a*), whereas all concentrations of GA reduced cell necrosis by >60% at 4 h (Fig. 2*b*). A concentration-effect comparison of GL and GA (Fig. 2*c*) demonstrates the superior protection afforded at all concentrations by GA.

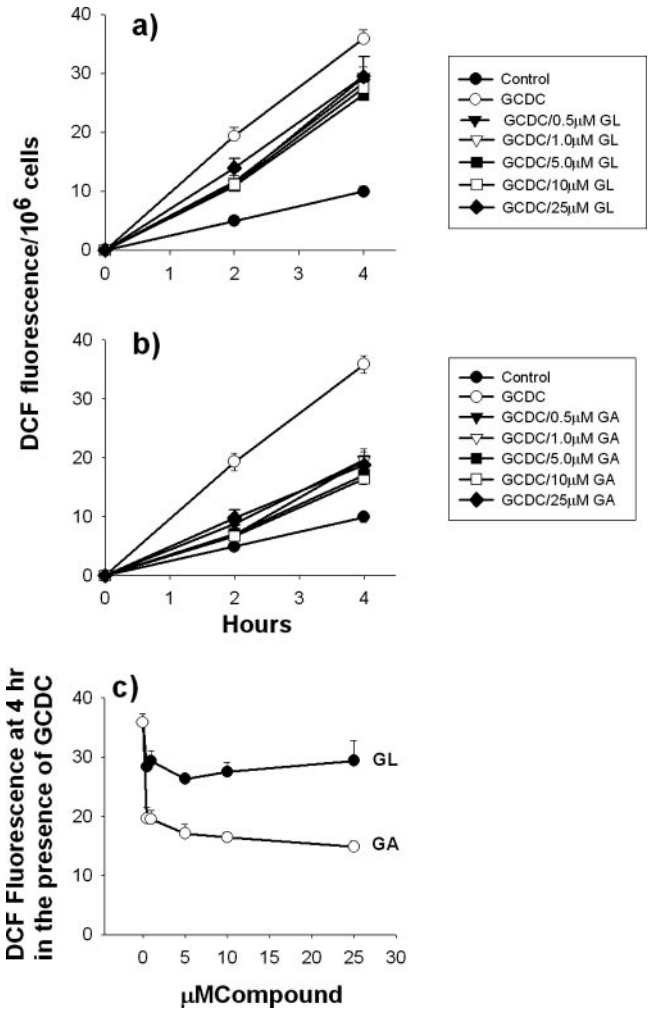

FIG. 1. **Effects of GL and GA on ROS generation in isolated rat hepatocyte suspensions exposed to GCDC.** Hepatocytes (10^6/ml) were loaded with 10 μM DCF-DA for 30 min prior to preincubation with various concentrations of GL (*a*) or GA (*b*) followed by exposure to 100 μM GCDC. Aliquots were removed at 2 and 4 h for DCF fluorescence, expressed as DCFein fluorescence/10^6 cells, as described under "Experimental Procedures." The 4 h DCFein values for GCDC-exposed hepatocytes are plotted *versus* concentrations of GL and GA (*c*). Results are from at least six separate experiments and are expressed as mean ± S.E.

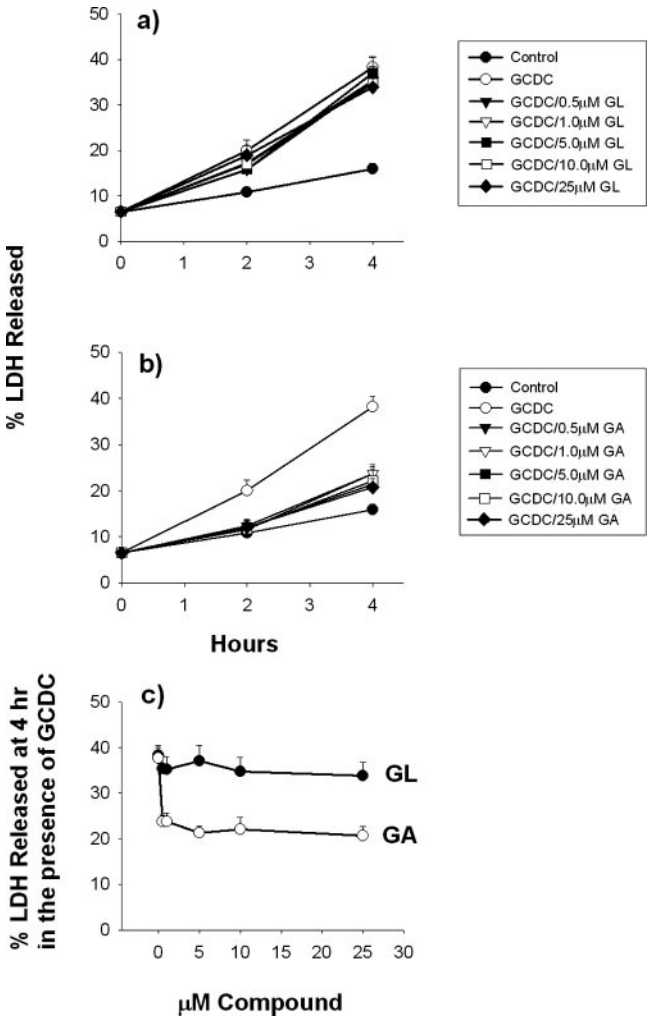

FIG. 2. **Effects of GL and GA on cellular necrosis in isolated rat hepatocyte suspensions exposed to GCDC.** Hepatocytes were preincubated with various concentrations of either GL (*a*) or GA (*b*) for 30 min prior to the addition of 100 μM GCDC. Aliquots were removed at 2 and 4 h and necrosis assessed as percent lactate dehydrogenase (*LDH*) released, as described under "Experimental Procedures." The 4-h percent lactate dehydrogenase released values for GCDC-exposed hepatocytes were plotted *versus* concentrations of GL and GA (*c*). Results are from at least six separate experiments and expressed as mean ± S.E.

The differential effects of GL and GA on hepatocytes were more dramatic when DAPI-stained hepatocyte nuclei were examined for apoptosis (Fig. 3). Hepatocytes treated with 100 μM GCDC underwent significant apoptosis by 4 h (31.5 ± 11.9% *versus* 1.6 ± 0.7% for control cells) (Fig. 4). Preincubating hepatocytes with 25 μM GL enhanced apoptosis by ~170–210% after 2 h incubation (Fig. 4*a*). In contrast, 25 μM GA significantly inhibited GCDC-induced apoptosis by >70% throughout the course of the experiment (Fig. 4*b*). A concentration-effect analysis of the effects of GL and GA on GCDC-induced apoptosis at 3 h (Fig. 4*c*) demonstrated that GL enhanced apoptosis at concentrations of 0.5 μM and above, whereas GA protected against apoptosis at ≥10 μM.

Previous experiments have demonstrated that GCDC causes a reduction of mitochondrial membrane potential (indicating the MPT) that precedes induction of apoptosis in hepatocytes (11, 15). Therefore, JC-1 fluorescence was used to determine the effects of GL and GA on bile acid induction of MPT in live hepatocytes. Hepatocytes exposed to GCDC for 3 h (Fig. 5*a*, *red* data line) showed a decrease in mitochondrial membrane potential (shift to left of JC-1 aggregate fluorescence curve) when compared with control cells (*blue* data line). The time course (Fig. 5, *b* and *c*) demonstrated a decrease in JC-1 fluorescence by 1 h. Preincubation with 10 μM GL (Fig. 5*, a* and *b, black* data line) failed to prevent the dissipation of membrane potential at any time point. However, pretreating cells with 25 μM GA (Fig. 5, *a* and *c*, *green* data line) significantly prevented the reduction in membrane potential for at least 3 h, commensurate with the protection offered against necrosis and apoptosis. GL and GA alone (Fig. 5, *a* and *c*, *gold* data line) had only a slight effect on membrane potential.

Effects of GL and GA on Changes in Caspase and MAPK Activation—Immunoblots of whole cell lysates indicated that procaspase 10 was reduced after 3 h of incubation with GCDC (Fig. 6*a*). This apparent activation of caspase 10 was prevented by 25 μM GA but not by 1 or 10 μM GL. Activation of caspase 10 previously has been shown to process executioner caspases 3 and 7 (23). As shown in Fig. 6*b*, caspase 3 existed predominantly in the native, uncleaved form (procaspase 3) in the absence of GCDC (*lane 1*). However, after 3 h GCDC reduced levels of procaspase 3. Preincubation of hepatocytes with GA prevented loss of procaspase 3, whereas GL yielded no protection at 1 μM, and at 10 μM GL increased the appearance of the

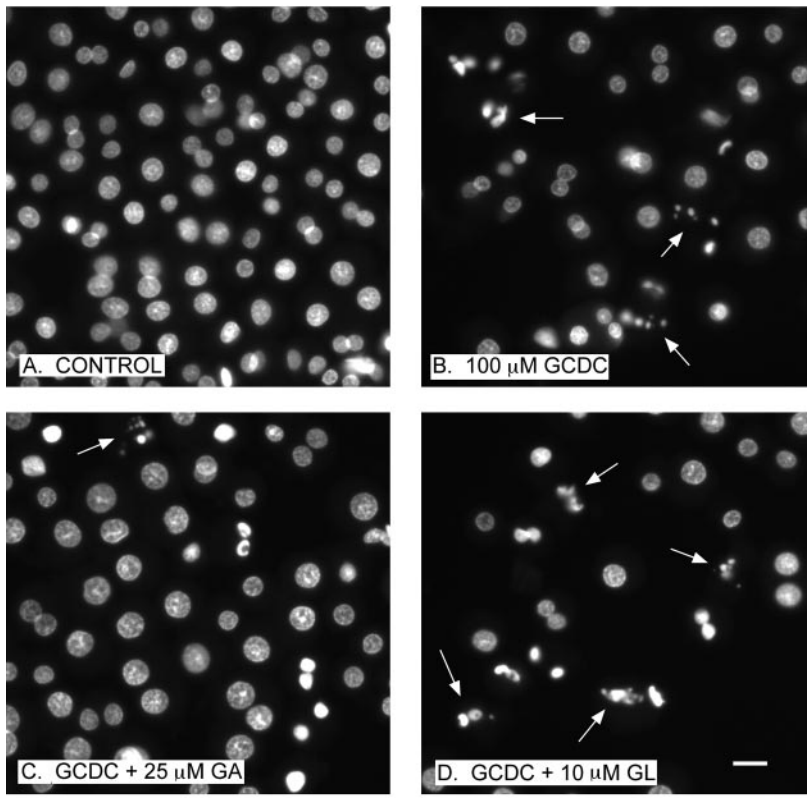

FIG. 3. **Fluorescence microscopy of hepatocyte nuclei labeled with DAPI.** Hepatocytes were incubated with no additions (*A*), with 100 μM GCDC alone (*B*), or in the presence of 25 μM GA (*C*) or 10 μM GL (*D*) for 3 h. After the incubation, cells were fixed, cytofuged onto a slide, and stained with DAPI for fluorescence microscopy. Only those cells that had fragmented nuclei or marginated chromatin (depicted by *arrows*) were considered apoptotic. *Scale bar* (in the *lower right corner*) = ~10 μm.

cleaved caspase 3. Similar results were observed by examining the cleavage of PARP, where GCDC promoted PARP cleavage, which was prevented by GA and potentiated by GL (Fig. 6*c*).

Caspase 9 is activated following cytochrome *c* release from mitochondria. Immunoblot analysis of cleaved caspase 9 revealed an increase of caspase 9 after incubation with GCDC (Fig. 6*d*), which was only mildly reduced by GA and was potentiated by 10 μM GL (Fig. 6*d*). In selected experiments, β-actin was probed to demonstrate equal loading of all lanes (Fig. 6*e*). Taken together, these data support the hypothesis that the anti-apoptotic effects of GA is primarily through a caspase 9-independent mechanism.

Activation of MAPK has been recently reported to be involved in cell signaling cascades involved in bile acid cytotoxicity (24, 25). We examined activation of the two members of the MAPK family implicated in bile acid toxicity, p38 MAPK and JNK; the latter is also a member of the SAPK family (Fig. 7). Band densities of phosphorylated MAPK were expressed relative to total MAPK levels and then adjusted to control samples, which were normalized to a value of 1.0. The effects of GL and GA on phosphorylation of p38 MAPK in GCDC-treated cells are shown in Fig. 7*a*. The ratio of phosphorylated to total p38 MAPK remains relatively unchanged by treatment with GCDC (Fig. 7*a*, *lane 2*), GA (*lane 3*), or GL (*lanes 4* and *5*), suggesting that apoptosis was not p38 MAPK-dependent. In Fig. 7*b*, the ratio of phosphorylated to total JNK density was increased by exposure to GCDC alone (1.9-fold, *lane 2*). Pretreatment with GA (Fig. 7*b*, *lane 3*) prevented JNK phosphorylation, whereas GL (*lanes 4* and *5*) had no significant effect. These data support a role for JNK activation during GCDC-induced apoptosis, suggesting that the anti-apoptotic effect of GA may be mediated by inhibition of the SAPK/JNK pathway.

Effects of GL and GA on Liver Mitochondria—ROS generation and induction of the MPT in liver mitochondria by bile acids have been implicated in hepatocellular death by necrotic and apoptotic mechanisms. Therefore, we next examined the direct effects of GL and GA on mitochondrial function. Incubation of purified liver mitochondria with 100 μM GCDC resulted in a linear increase in ROS generation (Fig. 8). Preincubation with GL inhibited ROS generation in a dose-dependent manner at low concentrations (0.1–1 μM), reaching a plateau at 1.0 μM GL, which reduced ROS generation by >60% at 10 min (Fig. 8*a*). GA reduced ROS generation >60% at all concentrations (0.1–10 μM) (Fig. 8*b*). These treatment effects were comparable with the cytotoxicity responses observed in Figs. 1 and 2, with GA exhibiting a greater antioxidative and protective effect than GL.

Next, the effects of GL and GA on GCDC-induced MPT in purified mitochondria were compared. As shown previously (11, 13), GCDC induced the MPT when incubated for 5 min with succinate-energized mitochondria (Fig. 9). In the current study, a dose-dependent decrease in the magnitude of the MPT was observed when mitochondria were preincubated with 0.1–1.0 μM GL (Fig. 9*a*), with a reversal of this effect as the concentration of GL was increased to 5 or 10 μM. GA inhibition of the MPT was almost identical to that observed with GL, including the reversal of protection observed above 1 μM (Fig. 9*b*). Neither GL nor GA (up to 25 μM) incubated alone with mitochondria induced the MPT (data not shown). Because of the magnitude of MPT inhibition by low (including submicromolar) concentrations of GL and GA, we compared these compounds against CsA, a direct blocker of the MPT (Fig. 9*c*). On an equimolar basis, both GL and GA offered protection against the GCDC-induced MPT almost equal to that provided by CsA.

Subsequent to induction of the MPT by GCDC, mitochondria released substantial amounts of cytochrome *c* (Fig. 9*d*). Preincubation with graded concentrations of GL and GA showed similar protection against loss of cytochrome *c*, paralleling the reduction of MPT magnitude (Fig. 9, *a* and *b*).

DISCUSSION

Licorice root has long been utilized as an herbal remedy against a variety of ailments in Asian cultures (26). Although the precise biological mechanisms responsible for these clin-

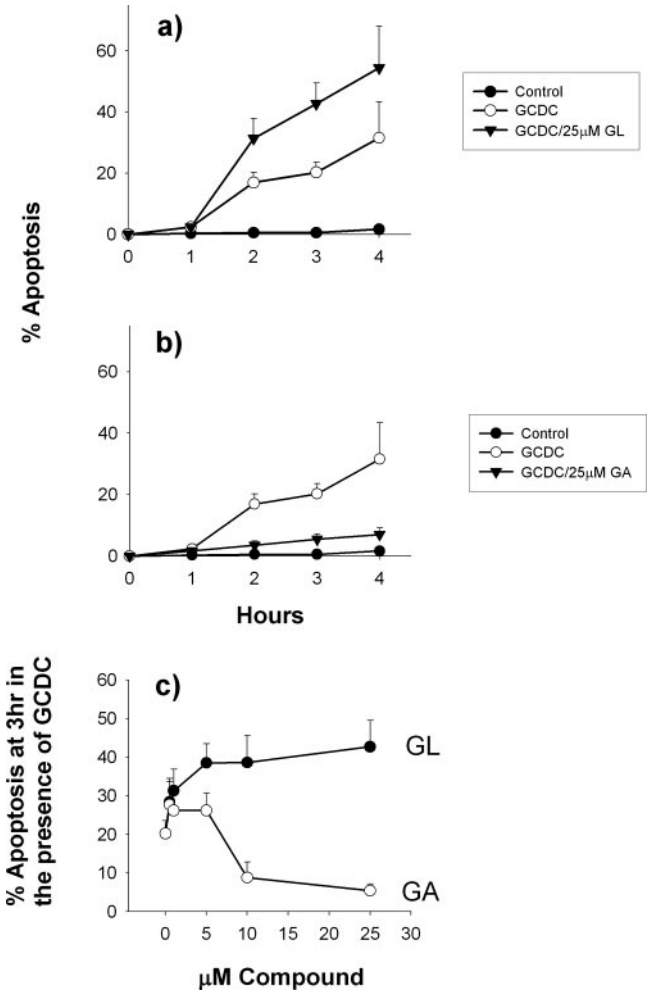

FIG. 4. **Effects of GL and GA on GCDC-induced hepatocyte apoptosis.** Hepatocytes were exposed to 100 μM GCDC for 4 h in the absence or presence of 25 μM GL (*a*) or GA (*b*). Aliquots were removed hourly for quantitation of apoptosis as described under "Experimental Procedures." The percent of apoptotic cells after 3 h of exposure to GCDC was plotted *versus* concentrations of GL and GA (*c*). Results are from at least six separate experiments and expressed as mean ± S.E.

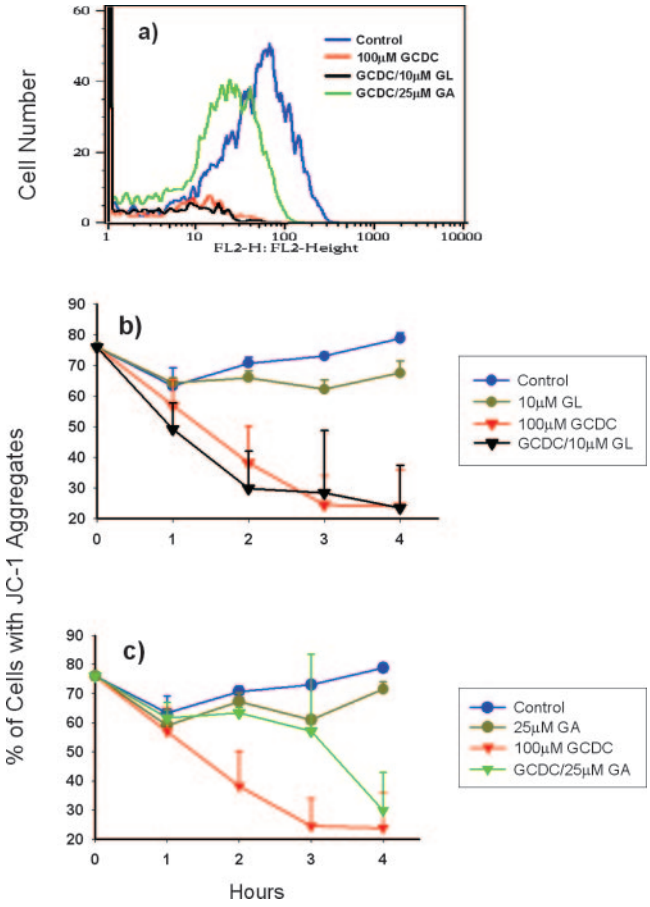

FIG. 5. **Effects of GA and GL on GCDC-induced mitochondrial depolarization in rat hepatocytes.** Isolated rat hepatocytes were treated with 100 μM GCDC alone (*red line*), or combined with 10 μM GL (*black line*) or 25 μM GA (*green line*). Aliquots were removed hourly and loaded with JC-1 and propidium iodide as described under "Experimental Procedures." In *a*, a representative plot of JC-1 aggregate fluorescence is shown after 3 h, indicating mitochondrial depolarization in GCDC-treated cells compared with control hepatocytes (*blue line*), which was prevented by GA but not GL. The time course of JC-1 aggregate formation is depicted in *b* and *c*, demonstrating protection by GA but not GL. Neither GL nor GA alone (*gold lines*) affected mitochondrial depolarization. Results are from three separate experiments and expressed as mean ± S.E.

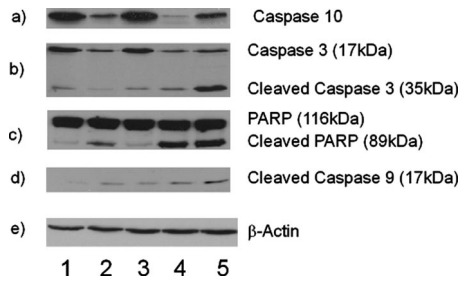

FIG. 6. **Immunoblot analysis of caspases and PARP from rat hepatocytes treated with GCDC.** Whole cell lysates obtained from hepatocytes after 3 h of incubation were separated by SDS-PAGE and immunoblotted as described under "Experimental Procedures." For each blot, the lane assignments were as follows: *lane 1*, control; *lane 2*, 100 μM GCDC; *lane 3*, 100 μM GCDC + 25 μM GA; *lane 4*, 100 μM GCDC + 1 μM GL; and *lane 5*, 100 μM GCDC + 10 μM GL. Blots were probed with antibodies raised against caspase 10 (*a*), caspase 3 (*b*), native and cleaved PARP (*c*), cleaved caspase 9 (*d*), and β-actin (*e*). These are representative results from 2–4 separate hepatocyte preparations.

ical benefits are unknown, evidence from experimental studies document that GL and its major metabolite by intestinal metabolism, GA, are protective in whole animals and cultured hepatocytes (18, 27). Several hypotheses have been put forward to account for the hepatic protection offered by these compounds including stimulation of cytochrome P-450 and glutathione *S*-transferase activities (27) or their activity as an antioxidant through glutathione preservation (18). Although these compounds are commonly used in herbal preparations purported to be of benefit in cholestatic liver disease (17), their biological effects in cholestatic liver injury have not been characterized. Therefore, the current study was performed to determine the effects of GL and GA on pathways involved in bile acid-induced cytotoxicity.

The results of this study reveal GL and GA to be potent modulators of bile acid-induced cytotoxicity with GL enhancing GCDC-induced apoptosis and GA significantly inhibiting both necrotic and apoptotic cell death. Micromolar concentrations of GL enhanced GCDC-induced activation of several pro-apoptotic pathways, including caspase 10 and JNK signaling. In contrast, GA inhibited these signaling pathways and afforded significant protection against cytotoxicity. This protective role of GA was consistent with its antioxidative effect, although other potential effects of GA (28, 29) were not explored. Interestingly, the potentiation of GCDC-induced apoptosis by GL was independent of its modest reduction of ROS generation. Importantly, the protective effect of GA in hepatocytes was

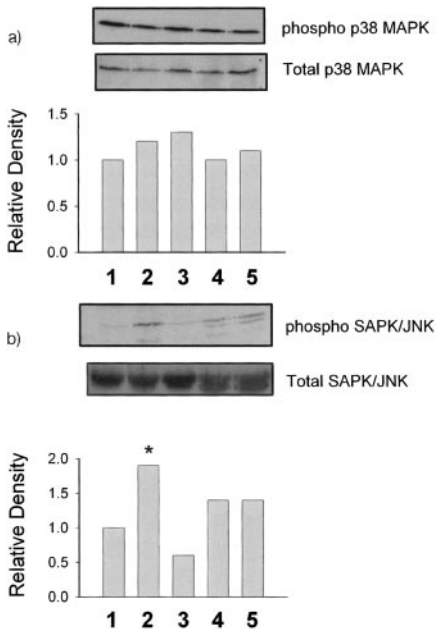

FIG. 7. **Immunoblot analysis of MAPK in rat hepatocytes treated with GCDC.** Whole cell lysates obtained from control hepatocytes after 3 h of incubation were separated by SDS-PAGE and immunoblotted as described under "Experimental Procedures." For each blot, the lane assignments were as follows: *lane 1*, control; *lane 2*, 100 μM GCDC; *lane 3*, 100 μM GCDC + 25 μM GA; *lane 4*, 100 μM GCDC + 1 μM GL; and *lane 5*, 100 μM GCDC + 10 μM GL. Blots were probed with antibodies raised against total and phosphorylated p38 MAPK (*a*) and total and phosphorylated SAPK/JNK (*b*). Levels of activation by GCDC in the absence or presence of GL or GA are graphically depicted in *bar graphs* and are expressed as the ratio of the relative density of phosphorylated/total protein, with control cells standardized to 1.0. The results are from three separate hepatocyte preparations. *, denotes statistical significance ($p < 0.05$) of control hepatocytes *versus* GCDC-treated cells.

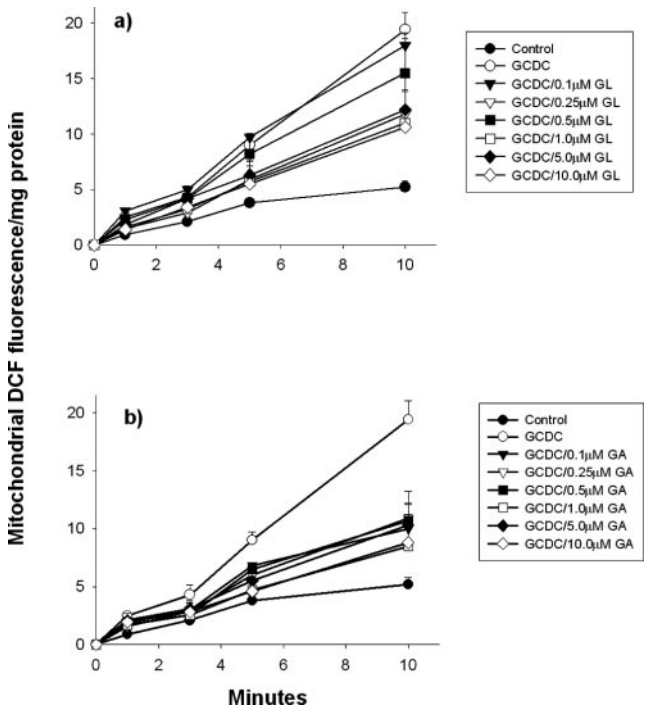

FIG. 8. **Effects of GL and GA on ROS generation in purified liver mitochondria treated with GCDC.** Percoll gradient-purified liver mitochondria were loaded with DCF-DA, preincubated with various concentrations of GL (*a*) or GA (*b*), and then incubated with 100 μM GCDC. Aliquots were removed at designated time points, and DCF fluorescence was expressed as DCFein fluorescence/mg of protein. Results are from 3–4 separate experiments and expressed as mean ± S.E.

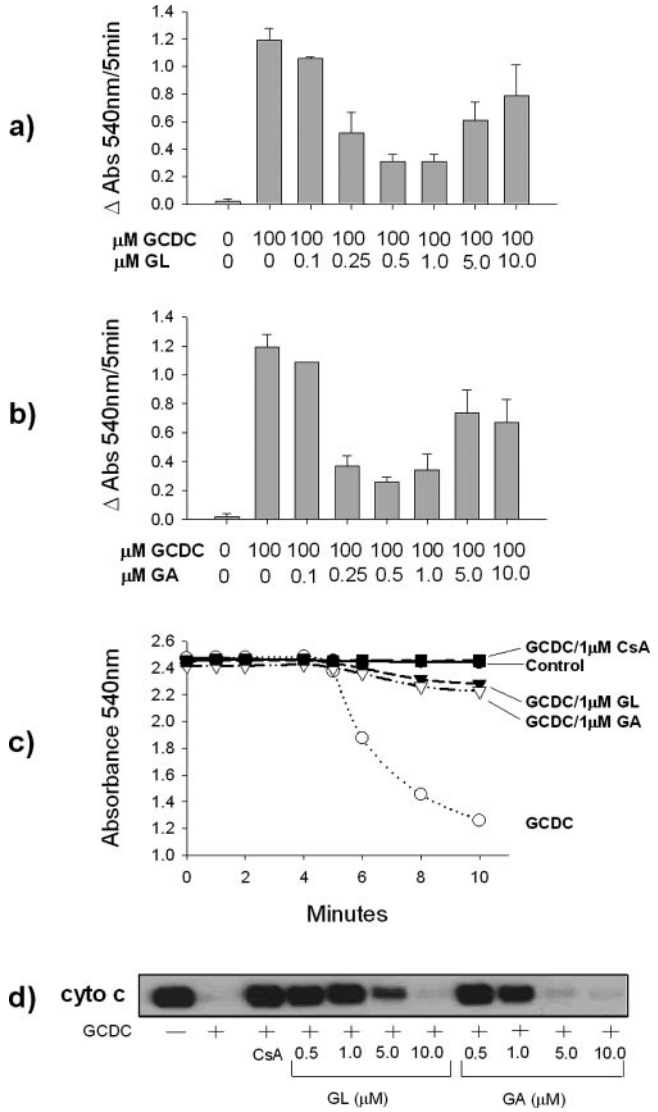

FIG. 9. **Effects of GL and GA on GCDC-induced MPT and cytochrome *c* release from purified mitochondria.** Rat liver mitochondria were preincubated for 10 min with 0–10 μM GL (*a*) or GA (*b*) prior to induction of MPT by 100 μM GCDC. Mitochondrial swelling was monitored at 540 nm as described under "Experimental Procedures." Results are from 3–4 separate experiments and expressed as mean ± S.E. In *panel c*, the inhibitory potency of GA and GL are compared with CsA in a representative experiment. After the 5-min incubation of mitochondrial with GCDC, mitochondria were isolated and immunoblotted for cytochrome *c* content (*d*) as described under "Experimental Procedures."

accompanied by inhibition of the MPT in live cells, ROS generation, cytochrome *c* release from mitochondria, and caspase 9 activation.

Previous studies have associated increased oxidative stress with the severity of bile acid-induced cytotoxicity in hepatocyte suspensions (15, 25) and in whole animals receiving parenterally administered bile acids (14). Correspondingly, oxidative stress and cytotoxicity were attenuated by antioxidants including α-tocopherol, β-carotene, or the coenzyme Q analog, idebenone (13, 15, 30). The relative degree of antioxidant activity of GL and GA (Fig. 1) correlated well with the capacity of each compound to suppress GCDC-induced cellular necrosis (Fig. 2). However, the potentiation of apoptosis by GL (Fig. 3) implicates activation of other apoptotic signaling pathways or inhibition of cell survival cascades. In contrast, GA continued to demonstrate marked anti-apoptotic effects even at concentrations as low as 0.5 μM. In prior studies of hepatocyte apoptosis,

Yoshikawa *et al.* (31) reported that GL inhibited tumor necrosis factor-α- but not Fas-dependent apoptosis in HepG2 cells at concentrations that significantly enhanced apoptosis in our study. However, ROS generation, mitochondrial function, and caspase activation were not addressed in that study (31). In the current study, the reduction of oxidant stress and the cytoprotective effect by GA were consistent with another study that reported an antioxidative role of GA in the amelioration of carbon tetrachloride-induced liver injury (18).

One well characterized caspase-dependent pathway responsible for bile acid-induced hepatocyte apoptosis requires death receptor activation of caspase 8 as a response to formation and aggregation of a death-induced signaling complex (DISC) (32). Upon activation of caspase 8, signaling through the mitochondrial pathways results in downstream caspase 3 cleavage, activating the nuclear enzyme PARP, which is responsible for nuclear degradation. A closely related homolog to caspase 8, caspase 10, is another target of Fas ligand and TRAIL-induced activation (33, 34) and has been reported to promote apoptosis in certain cell types (35, 36). Caspase 10 exists as four known isoforms and is expressed in many tissues including liver and skeletal muscle (23). Despite its being implicated as an inducer of apoptosis, the role of caspase 10 in bile acid-induced cytotoxicity has not been examined. In our studies, procaspase 10 levels in rat hepatocyte suspensions underwent increased proteolysis in the presence of GCDC, which was prevented by GA. In a recent study, Higuchi *et al.* (37) found no activation of caspase 10 by GCDC alone but found that co-incubation of GCDC with TRAIL, a death receptor cell signaling agent, promoted caspase 10 cleavage. There are differences between our study and that of Higuchi *et al.* (37) that could account for the differing effects of bile acids on caspase 10; those authors used HuH-7 cells transfected with a sodium-dependent transporting polypeptide in culture for 12 h, and our study utilized freshly isolated rat hepatocytes. The role of caspase 10 in bile acid-induced cytotoxicity requires further study.

Previous studies indicate that activation of p38 and JNK, via the SAPK pathway, is associated with bile acid-induced apoptosis (24, 25, 38), whereas activation of ERK may suppress apoptosis (39, 40, 44). Both p38 and JNK, activated by stress and inflammatory stimuli, regulate AP-1 transcription factor and its component, c-Jun, by phosphorylation reactions (41). In our study, JNK activation, commensurate with oxidative stress, was a key signal in GCDC cytotoxicity. It has been proposed that oxidative stress itself is responsible for JNK activation (25, 42). This sequence of events is supported by the differential effects of GA and GL on ROS generation and JNK activation. In addition, in our model the dependence of caspase 10 on ROS generation and JNK activation is consistent with the observation of Chaudhary *et al.* (43), suggesting that increased ROS generation may be the upstream event that triggers JNK and caspase activation in bile acid-induced hepatocyte toxicity.

In addition to death receptor-initiated cytotoxicity, bile acids also promote cell death by direct effects on mitochondrial structure and homeostasis (12, 15, 45, 46). Consistent with previous findings (15, 25), GCDC increased generation of ROS, caused mitochondrial depolarization, and activated caspase 9 in rat hepatocytes. GA, providing a more robust antioxidative effect than GL, prevented this apoptotic pathway, whereas GL failed to afford protection. However, in contrast to their dichotomous effects on GCDC toxicity in hepatocytes, submicromolar concentrations of GL and GA similarly blocked the MPT and release of cytochrome *c* in purified liver mitochondria exposed to GCDC. Thus the differential effects of GA *versus* GL on cytotoxicity do not appear to be related to direct effects on mitochondria. However, it must be emphasized that although cellular uptake of GL and GA has been characterized previously (47, 48), mitochondrial uptake, transport, and metabolism have not been examined.

Several factors must be considered prior to examining the possible benefical or modulatory roles of these compounds in hepatobiliary disorders, including achievable tissue concentrations, mode of administration, metabolism and potential toxicity. Orally ingested GL undergoes hydrolysis by β-glucuronidase in the intestine resulting in GL monoglucuronide and, ultimately, GA, which is absorbed into the bloodstream (49). Intravenous administration of GL-containing compounds results in the appearance of both GL and GA in the plasma of animals (50), although conversion of GL to GA is believed to occur primarily in the mucosa of the small intestine (51). Intravenous administration of GL in healthy men and in hepatitis C patients achieved maximal plasma concentrations of 29 μg/ml (approx 36 μM) (52) and 120 μM (53), respectively, whereas orally administered GL yielded no detectable plasma GL and only very low (<200 ng/ml) concentrations of GA (52). In another study, plasma GA levels reached 10 μM in humans ingesting licorice (54), similar to the protective concentrations of GA in our study.

In conclusion, low concentrations of GL resulted in enhanced bile acid-induced apoptosis of isolated hepatocytes through activation of caspases and the SAPK pathway member, JNK. Conversely, GA inhibited these pathways, prevented bile acid-induced mitochondrial depolarization, reduced oxidative stress, and protected against apoptosis and necrosis. Further evaluation of these compounds are warranted in regard to a potential role in treating cholestatic liver disease and other liver diseases associated with increased oxidative stress.

Keywords: Superoxide radical; DNA; Hydrogen peroxide; Chinese hamster ovary cell.

Summary

The rate of oxyradical generation by a xanthine oxidase–xanthine system to acutely cause DNA strand breakage in Chinese hamster ovary cells was studied in a phosphate-buffered saline system. DNA strand breakage, measured by a fluorometric procedure, was found to increase curvilinearly as a function of oxyradical generation. Results of studying the ability of 5 mM mannitol, 10 mM dimethylthiourea, 300 μg superoxide dismutase/ml, or 1 mg catalase/ml to interfere with DNA damage at a high rate of oxyradical production best supported a hydrogen peroxide-promoted mechanism for DNA breakage.

Evidence presented by Weitzman et al. (1985) using human neutrophils as oxyradical generators and supported by studies of Zimmerman and Cerutti (1984) suggests that the production of active oxygen species in the presence of living cells can promote the evolution of cell transformation processes which lead to neoplasia. Since microbial infections have been associated with higher incidences of cancer in humans (Mackowiak, 1987) and since normal body defense mechanisms are well known to involve phagocytes which produce active oxygen species used to inactivate these microbes, we have undertaken studies to define the DNA damage produced by the generation of oxyradicals in a system of living cells. We have also attempted to determine what active oxygen species may be primarily involved in the DNA-damaging process.

Recent studies by Weitberg et al. (1983, 1985)

and Sofuni and Ishidate (1984) have suggested that oxyradical generation in systems containing Chinese hamster ovary (CHO) cells or Chinese hamster fibroblasts, respectively, can produce DNA damage in these cells as evidenced by increased numbers of sister-chromatid exchanges and various other chromosomal aberrations. In these studies, either stimulated human granulocytes or xanthine oxidase systems were used as oxyradical generators; the effect of these radicals on cell chromosomes was measured 24 or more hours later. Although effects on cellular chromosomes were reported in these studies, the time periods used, lack of available information regarding actual quantities of oxyradicals produced, and failure to use purified xanthine oxidase make it difficult to distinguish what acute effects oxyradical may have had on cellular DNA.

In this investigation we have applied a fluorometric procedure to study the acute effects of oxyradicals on DNA strand breakage in CHO cells. Commercially available xanthine oxidase was preliminarily chromatographed to remove contaminating proteases and standardized by spectrophotometric methods.

Materials and methods

Ham's F-10 medium, fetal bovine serum (FBS), Dulbecco's phosphate-buffered saline (PBS), and antibiotics were products of Gibco Laboratories; ethidium bromide (CAS 1239-45-8), xanthine oxidase (buttermilk), xanthine (CAS 69-89-6), mercaptoethanol (CAS 60-24-2), cytochrome *c* type VI (CAS 9007-43-6), superoxide dismutase, catalase, cyclohexane diaminetetraacetate, sodium laurylsulfate (CAS 151-21-3), urea (CAS 57-13-6), and sodium dithionite (CAS 7775-14-6) were products of Sigma Chemical Co. Pentex bovine serum albumin (BSA) was from Miles Laboratories, Sephadex from Pharmacia, and all other chemicals used were reagent grade. All solutions were prepared in high purity (Milli-Q) water.

CHO cells were grown in modified Ham's F-10 medium containing 10% FBS with 100 μg kanamycin sulfate/ml. Culture flasks (75 cm^2) were seeded with $2–3 \times 10^5$ cells that had a doubling time of 12–14 h. All experiments were carried out at the time cells reached confluence.

Xanthine oxidase was freed of protease activity by the method of Waud et al. (1975). This was undertaken not only to prevent the effects of the protease on subunit structure and activity of xanthine oxidase, but also to prevent possible effects of protease activity on cell morphology and function that have been described by Agar and Gordon (1984) and might otherwise contribute to apparent damage caused by active oxygen. The final preparation was suspended in Dulbecco's PBS containing 0.1% BSA. Preparation activity was standardized at 25 °C by the method of Hart et al. (1970). Superoxide anion production by the xanthine oxidase–xanthine system used for exposing cells to oxyradicals was determined by measuring initial reduction rates of ferricytochrome *c* in the same system under conditions used for cell treatment. The reaction mixture of 3.0 ml contained 2×10^{-5} M ferricytochrome *c*, 0.1 mM xanthine, and xanthine oxidase in Dulbecco's PBS. Cytochrome reduction was followed at 550 nm, and the rate of superoxide production was carried out by using a millimolar absorption coefficient of 29.5 for cytochrome *c*. The reaction was begun by adding substrate to the system pre-equilibrated to a temperature of 37 °C.

Monolayers of confluent CHO cells were washed with Dulbecco's PBS and incubated in Dulbecco's PBS for 30 min at 37 °C in the presence of varying concentrations of xanthine and/or xanthine oxidase. After incubation, the reaction mixture was poured off, and the cell layer was washed 3 times with PBS. After washing, cells were harvested by trypsinization for 2 min. Cells were finally washed in growth media containing 10% FBS followed by 2 washes in PBS. The final cell pellets were placed on ice and resuspended in ice-cold 0.25 M sucrose–10 mM sodium phosphate–1 mM magnesium chloride (pH 7.4). This preparation was used for analyzing DNA double-strand content.

The fluorometric analysis of cellular double-stranded DNA was conducted by a modification of the method of Birnboim and Jevcak (1981). Under the conditions reported by these authors, we found that only 20% of the cellular double-stranded DNA remained. As a result, their procedure was re-examined and modified to yield approximately 74% double-stranded DNA after al-

kali diffusion-induced DNA unwinding. This degree of recovery could be attained provided that 0.17 M NaOH was substituted for the 0.2 M NaOH originally reported. In addition, the incubation conditions were modified; a single, 30-min diffusion period at 0 °C was used to promote uncoiling of short-length DNA strands produced by cellular oxyradical exposure. We found 0.25 M sucrose–10 mM sodium phosphate–1 mM magnesium chloride (pH 7.4) to be adequate for initial cellular suspension. Cell suspensions used for the uncoiling procedure and all subsequent steps used for uncoiling were carried out in a darkened room. The final fluorescence was read by using an Aminco–Bowman fluorometer with an excitation wavelength of 520 nm; emission was determined at 590 nm.

The effects of various radical removing or quenching agents were studied in a system identical to that described for studying oxyradical effects on confluent CHO cells. Catalase (1 mg/ml), superoxide dismutase (300 μg/ml), mannitol (5 mM), or dimethylthiourea (10 mM) were incorporated into PBS before oxyradical formation was induced by adding xanthine to the xanthine oxidase system. Incubation times and other conditions and manipulations were identical to those described above.

Tests for statistical significance were carried out using the Student's *t*-distribution analysis. Calculations were performed during a Compucorp 344 computer.

Results

Fig. 1 shows the percentage of double-stranded DNA remaining in CHO cells as a function of the initial rate of superoxide radical generated by the xanthine oxidase–xanthine system used. Points in the figure represent the mean values of 8 determinations for control or for systems containing 0.1, 0.25, or 0.5 units of xanthine oxidase ml. Span limits above and below each point represent the standard deviation. Xanthine, 0.1 mM, served as substrate in a system that contained 1 μmole of total xanthine. A 30-min incubation period was allowed so that approximately the same quantity of superoxide anion was produced by each enzyme system used.

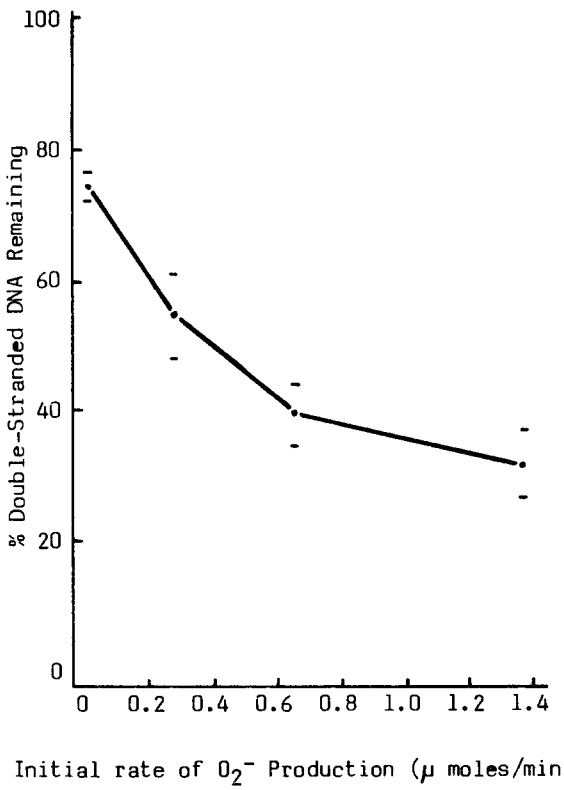

Fig. 1. Recovery of double-stranded DNA from CHO cells exposed to increasing rates of superoxide anion production in PBS.

The amount of DNA damage produced increased curvilinearly as a function of the initial rate of superoxide anion production. The control cell system contained no xanthine or xanthine oxidase and yielded a recovery of $74.3 \pm 2.09\%$ (mean $\pm$ 1 S.D.) double-stranded DNA. At the highest level of superoxide anion generation used, only $32.0 \pm 4.01\%$ double-stranded DNA was recovered from the CHO cell system. At each rate of superoxide anion production used there was a significantly lower recovery of double-stranded DNA ($P < 0.001$) than for the control. DNA recoveries from control systems containing 0.1 mM xanthine, 0.1 unit xanthine oxidase/ml, or 0.5 unit xanthine oxidase/ml in PBS were $65.5 \pm 3.97\%$, $67.9 \pm 2.56\%$, and $66.4 \pm 3.09\%$, respectively. Each of these systems showed a significantly lower recovery than that noted for the buffer control ($P < 0.001$) and a significantly higher recovery than that noted for complete systems containing

xanthine and xanthine oxidase ($P < 0.001$). There were no differences in DNA recoveries found in the controls containing xanthine or xanthine oxidase in PBS. Complete systems containing PBS with xanthine and xanthine oxidase each showed DNA recoveries that were significantly different from the others ($P < 0.001$, $P < 0.01$ for system containing 0.25 unit xanthine oxidase/ml vs. system containing 0.5 unit xanthine oxidase/ml). The initial rate of superoxide anion production could not be further increased by increasing xanthine concentration in the system. This was shown spectrophotometrically with the ferricytochrome assay system and the temperature used for carrying out the cell studies. We did not use higher concentrations of xanthine oxidase in our studies because attempts to use xanthine oxidase at concentrations of 1 unit/ml were associated with signs of cellular damage as noted by the trypan blue exclusion test.

To establish conditions for studying the effects of radical-trapping agents on the recovery of double-stranded DNA from CHO cells, we first examined these agents' effects on ferricytochrome reduction in the system described previously. We slowed the reaction rate to a more easily examined one by performing the studies at 25°C. When ferricytochrome reduction rate was studied in the standard system, the rate of reduction appeared to be counteracted by a back reaction of oxidation apparently catalyzed by a product resulting from the reaction occurring between xanthine and xanthine oxidase (Fig. 2, C). Incorporating 5 mM mannitol (M) or 10 mM dimethylthiourea (D) into the system caused an increase in the total reduction of ferricytochrome measured. Each agent was, in turn, associated with a delay in ferrocytochrome back-oxidation. Dimethylthiourea produced a greater effect than did mannitol.

We presumed that the back-oxidation was caused by the build up of hydrogen peroxide generated in the system from superoxide anion dismutation occurring at rates similar to the reduction of ferricytochrome *c*. To test this we examined the same system after adding 50 μg of catalase. When this was done, identical curves for reducing ferricytochrome *c* were noted for the control system, with or without the addition of either 5 mM mannitol or 10 mM dimethylthiourea. The kinetics of the reaction with catalase in the system are illustrated in Fig. 3. When catalase was present, there was no ferrocytochrome *c* back-oxidation, and all of the ferricytochrome *c* was found to be relatively quickly reduced.

Ferricytochrome *c* reduction by the xanthine–xanthine oxidase system in the presence of catalase was almost completely inhibited when sufficient superoxide dismutase was added. Maximum inhibition was noted when 150 μg of superoxide dismutase were added, and the reduction curve it

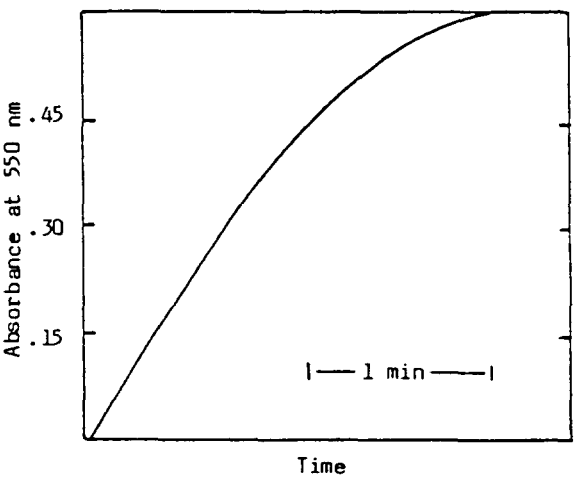

Fig. 3. Reduction of ferricytochrome *c* by a xanthine–xanthine oxidase system containing 50 μg of catalase in PBS.

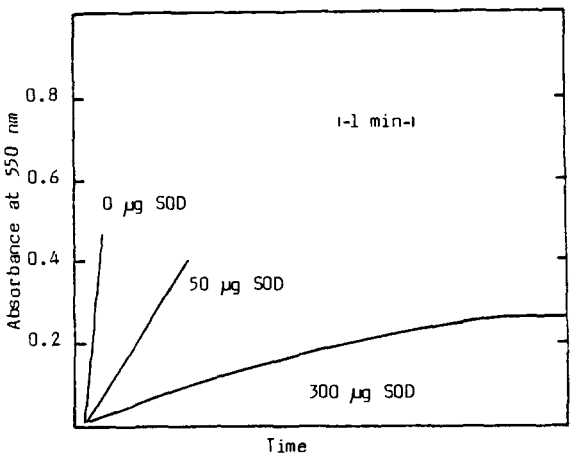

Fig. 4. Effect of superoxide dismutase (SOD) on the reduction of ferricytochrome *c* by a xanthine–xanthine oxidase system containing 50 μg catalase in PBS.

produced was identical to that seen when either 300 μg or 600 μg of superoxide dismutase was added (cf. Fig. 4). Residual reduction of ferricytochrome in the xanthine × xanthine oxidase system is caused by the presence of deflavo xanthine oxidase within these preparations. This was recognized by McCord and Fridovich (1969).

We next utilized these various systems to examine the effect of the radical-trapping agents on the recovery of double-stranded DNA from CHO cells. To ensure adequate catalase activity, we further increased the amount of catalase used to 1 mg/ml. The results of these studies are given in Table 1. In each case 6 separate studies were done, and the results represent the means ± 1 S.D. for each condition. To place maximum stress on each protective agent used, we used the maximum quantity of xanthine oxidase used previously (0.5 unit/ml). Once again a marked drop in recoverable double-stranded DNA similar to that previously seen, was noted. Each addition of the various agents to the system caused a significant protective effect, with maximum protection being granted by the system containing catalase. In this case, the percentage of recoverable double-stranded DNA was not different from that seen in the control ($P > 0.2$). Superoxide dismutase gave the poorest protection of all agents used; however, its effect was still significant ($P > 0.001$, < 0.01). The order of protective effect was catalase greater than catalase plus superoxide dismutase ($P > 0.1$)

TABLE 1

THE EFFECT OF VARIOUS AGENTS ON THE RECOVERY OF DOUBLE-STRANDED DNA FROM CHO CELLS INCUBATED WITH 0.5 UNIT OF XANTHINE OXIDASE (XO)/ml AN 0.1 mM XANTHINE (X) IN PBS

System	Double-stranded DNA recovered (%) (mean ± S.D.)
Control	75.3 ± 3.07
XO + X	35.1 ± 4.44
XO + X + 5 mM mannitol	63.3 ± 8.98
XO + X + 10 mM dimethylthiourea	54.1 ± 6.90
XO + X + 300 μg superoxide dismutase	51.3 ± 9.31
XO + X + 1 mg/ml catalase	71.6 ± 9.43
XO + X + 300 μg superoxide dismutase + 1 mg/ml catalase	68.0 ± 3.34

greater than mannitol ($P > 0.2$) greater than dimethylthiourea ($P > 0.05$, < 0.1) equals superoxide dismutase. Mannitol's effect was significantly greater than that produced by superoxide dismutase ($P < 0.05$) as were the effects of catalase with or without superoxide dismutase ($P < 0.01$). Systems containing catalase were also significantly more effective in protecting cellular double-stranded DNA than was the system containing dimethylthiourea ($P < 0.01$).

Discussion

The method employed in these studies for measuring DNA damage relies on the principle that ethidium bromide binds selectively to double-stranded DNA and not to single-stranded DNA produced when short duplex regions of double-stranded DNA are destabilized by alkali. When applied to a study of CHO cells exposed to varying rates of superoxide anion production caused by xanthine interaction with varying amounts of xanthine oxidase, a curvilinear decrease in the amount of remaining double-stranded DNA occurred as the rate of oxyradical generation was increased. The recovery of double-stranded DNA decreased significantly at each rate of superoxide radical generation used. Because each system gave

sufficient time for all xanthine to be utilized, the increased damage to DNA observed was not the result of total superoxide anion generated but rather resulted from the rate of its generation within the system. These results imply that cell defense mechanisms were operative in protecting cellular DNA and that their ability to do so was a function of the cells' exposure rate to oxyradical species involved. This interpretation is consistent with the observation of Cantoni et al. (1986), who recently observed that CHO cells can effectively remove the DNA strand breakage activity of hydrogen peroxide when cells are incubated with this oxidizing agent. Hydrogen peroxide or a derivative thereof could be the DNA strand-breaking agent here, because superoxide anion generated in the system is known to readily disproportionate in aqueous systems to yield hydrogen peroxide (cf. McCord and Fridovich, 1969). Unlike studies previously mentioned, we purified commercially available xanthine oxidase to remove contaminating proteases; therefore, protease action during superoxide anion generation by the xanthine–xanthine oxidase system could not have contributed to the results.

Although previous studies have indicated that DNA damage in CHO cells can be produced by oxyradical generation external to the cells, relating the damage produced to the actual rate of oxyradical generated was not attempted. McLean et al. (1982) studied this response effect using increasing quantities of radiation exposure to acutely generate oxyradicals in a human white blood cell system and showed a curvilinear effect on leukocyte DNA similar to that noted here. Our studies and those of McLean et al. (1982) imply that approximately 30% of the DNA contained within both human leukocytes and CHO cells is not susceptible to DNA damage at radical generation rates that do not cause appreciable cell death. The effects of oxidizing agents may induce cellular changes that eventually limit the oxidizing agent's access to cell DNA. Schraufstatter et al. (1986), reporting hydrogen peroxide's effects on DNA strand breakage in P388D_2 murine macrophages and human lymphocytes, found that the maximum DNA strand breakage induced by increasing concentrations of hydrogen peroxide approached a level of approximately 80% of the total double strands available for ethidium bromide binding.

The xanthine oxidase–xanthine system used in these studies generates superoxide anion as its primary product; hydrogen peroxide is produced as a secondary product by disproportionation in the aqueous system. We used the system of McCord and Fridovich (1969) to show this and to demonstrate that a reoxidation of ferrocytochrome *c* occurs after the initial ferricytochrome *c* reduction by superoxide anion. To prepare for our studies on radical quenching agent's effects on DNA strand breakage in CHO cells, we first looked at the kinetics of the ferricytochrome *c* reduction in the presence of xanthine oxidase at the maximum concentration of xanthine oxidase used for producing DNA damage. Both mannitol and dimethylthiourea were capable of delaying cytochrome reoxidation, and dimethylthiourea showed greater activity in doing so than did mannitol at the concentrations to be used. Catalase completely prevented the reoxidation, thereby implicating hydrogen peroxide as the active agent in this reoxidation. As expected, superoxide dismutase, at sufficient concentration, completely prevented ferricytochrome *c* reduction.

To obtain some information on the active oxygen species probably responsible for the DNA damage induced by the xanthine oxidase–xanthine system, we utilized the aforementioned agents at the concentrations used in our spectrophotometric system to determine their effects, if any, on preventing cellular DNA damage. All agents proved to be effective, but only catalase appeared to completely prevent DNA damage. Superoxide dismutase, at a concentration that completely prevented ferricytochrome *c* reduction in a soluble system, showed the least effect in preventing DNA damage and appeared to slightly promote DNA damage when it was incorporated into the system with catalase. These findings strongly suggest that hydrogen peroxide, or some derivative thereof, is a principal contributor to the DNA damage observed.

Because it has been well recognized that both superoxide anion and hydrogen peroxide can interact in the presence of a metal catalyst to form hydroxy radical via a Haber–Weiss-type reaction (Halliwell and Gutteridge, 1986), we investigated the effect of two known hydroxy radical quenchers

on this system. We chose these two agents primarily because one – namely, mannitol – shows comparatively low reactivity toward hydroxyl radical (Dorfman and Adams 1973), whereas the other (dimethylthiourea) not only shows marked reactivity toward hydroxyl radical but also appears to be relatively nontoxic to cells (Fox, 1984). These two agents were studied at concentrations that, by our spectrophotometric findings, also retarded reoxidation of ferrocytochrome *c* to the oxidized form. In the latter case, dimethylthiourea appeared to be more effective in retarding the reoxidation than did mannitol.

When the effect of 5 mM mannitol was compared with the effect of 10 mM dimethylthiourea in the xanthine–xanthine oxidase system that produced the greatest DNA damage, the mannitol apparently gave the best protection, although its protection level was not significantly greater than that seen for dimethylthiourea ($P > 0.05$, < 0.10). However, its effect was significantly greater than that seen for superoxide dismutase, whereas that of dimethylthiourea was not. Dimethylthiourea's effect was significantly less than that given by catalase ($P > 0.001$, < 0.01), whereas mannitol's effect, although less than that seen with catalase, did not reach a level of significance ($P > 0.1$). These results apparently indicate that mannitol expresses its effect via a mechanism other than reaction with hydroxyl radical. This may be related to mannitol's ability to bind to hydrogen peroxide (Halliwell and Gutteridge, 1986), which could conceivably impair hydrogen peroxide's ability to diffuse into the cell, and produce its effect on arrival.

These data best support a role for hydrogen peroxide, rather than for superoxide anion in producing of DNA strand breakage in CHO cells. The rate of hydrogen peroxide production appears to be an important factor and this is related to the rate of superoxide anion production from the xanthine oxidase–xanthine system used. The complete inhibition by catalase, the partial inhibition by a dithiourea compound that can react with hydrogen peroxide (Halliwell and Gutteridge, 1986), and the partial inhibition of the effect by mannitol, which can bind hydrogen peroxide, are consistent with this conclusion. However, because superoxide dismutase did cause some strand breakage inhibition, the concept that superoxide anion may play a contributory role — perhaps through an effect via a Haber–Weiss-type reaction — is supported. Hydroxyl radical derived either from the intracellular metabolism of hydrogen peroxide and superoxide anion or the intracellular metabolism of hydrogen peroxide via iron-linked mechanisms (Halliwell and Gutteridge, 1986) may be the primary functional agents involved here in DNA strand breakage. These are also generated by high-energy radiation, i.e., X-rays or γ-rays, which are known to induce DNA damage. In view of these results, it follows that acute DNA damage caused by active oxygen species may be the inciting event that can lead to observed chromosome damage and realignment described for a variety of neoplastic tissues. The relationship of the oxyradical production rate to DNA strand breakage and its relationship to observable chromosome damage, is to be the subject of investigation.

Abstract

Excessive consumption of alcoholic beverages is a serious cause of liver disease worldwide. The metabolism of ethanol generates reactive oxygen species, which play a significant role in the deterioration of alcoholic liver disease (ALD). Antioxidant phytochemicals, such as polyphenols, regulate the expression of ALD-associated proteins and peptides, namely, catalase, superoxide dismutase, glutathione, glutathione peroxidase, and glutathione reductase. These plant antioxidants have electrophilic activity and may induce antioxidant enzymes *via* the Kelch-like ECH-associated protein 1-NF-E2-related factor-2 pathway and antioxidant responsive elements. Furthermore, these antioxidants are reported to alleviate cell injury caused by oxidants or inflammatory cytokines. These phenomena are likely induced *via* the regulation of mitogen-activating protein kinase (MAPK) pathways by plant antioxidants, similar to preconditioning in ischemia-reperfusion models. Although the relationship between plant antioxidants and ALD has not been adequately investigated, plant antioxidants may be preventive for ALD because of their electrophilic and regulatory activities in the MAPK pathway.

Key words: Electrophile; Mitogen-activating protein kinase; Plant antioxidants; Reactive oxygen species; Preconditioning

Core tip: The metabolic process of ethanol generates reactive oxygen species, which play a significant role in the deterioration of alcoholic liver disease (ALD). Antioxidant phytochemicals, such as polyphenols, upregulate the expression of antioxidant enzymes and peptides *via* the Kelch-like ECH-associated protein

1-NF-E2-related factor-2 pathway, which leads to antioxidant responsive elements in animal models. Furthermore, these antioxidants alleviate cell injury caused by oxidants or inflammatory cytokines *via* impairment of hyperactivation of mitogen-activating protein kinase pathways, similar to preconditioning in ischemia-reperfusion models. Although the relationship between plant antioxidants and ALD has not been adequately investigated, plant antioxidants may be preventive for ALD.

INTRODUCTION

Humans are surrounded by many chemicals, including nutrients, phytochemicals, food additives, pharmaceuticals, and drugs. Although the intestine and liver absorb and metabolize many types of chemicals[1] for utilization or detoxification[2], some become more toxic once metabolized[3]. Ethanol, which is a component of alcoholic beverages, is one of the most common and abundant chemicals in daily life. Consuming ethanol can be relaxing and provides other benefits, but excessive drinking can be harmful physically and mentally and may decrease quality of life. Moderate consumption of alcohol has been shown to reduce the risks of cardiovascular disease[4] and non-alcohol fatty liver disease[5]. With moderate intake, most ethanol is oxidized by alcohol dehydrogenase and catabolized to acetaldehyde, which is subsequently catabolized to acetate *via* aldehyde dehydrogenase in the mitochondria. However, with binge drinking, ethanol is predominately metabolized to acetaldehyde *via* cytochrome P450, family 2, subfamily E, polypeptide 1 (CYP2E1), which comprises a microsomal ethanol-oxidizing system[6] that is involved in the generation of reactive oxygen species (ROS)[7-9]. Despite much evidence demonstrating a role for CYP2E1 in alcoholic liver disease (ALD), several of our studies have demonstrated that consumption of ethanol-containing diets significantly increased hepatic CYP2E1 levels without significantly affecting plasma alanine aminotransferase (ALT) activity (unpublished data). These findings support the existence of a potent endogenous antioxidant system that can prevent potential damage *via* the excessive expression of CYP2E1[10].

Binge drinking may cause liver injury, as demonstrated by increased blood levels of ALT, aspartate aminotransferase (AST), and/or lactate dehydrogenase (LDH)[11-14] and lipid accumulation in the liver-alcoholic fatty liver[12,13,15,16]. Hepatic functions are gradually lost with the progression of ALD[11], which is one of the most critical causes of cirrhosis[11,17]. Three mechanisms have been proposed to cause alcoholic liver injury: (1) acetaldehyde toxicity[18]; (2) metabolic generation of ROS or exposure to oxidative stress[10,19-21]; and (3) provocation of an immune response that causes oxidative stress in hepatocytes[13,22-24]. ALD patients appear to exhibit oxidative stress[11]; thus, increasing defense activities against this stress is important in the prevention of ALD.

In mammals, ROS is scavenged by antioxidant enzymes, such as superoxide dismutase (SOD) and catalase, and antioxidant substances, such as vitamins and glutathione (GSH) in collaboration with glutathione peroxidase (GPx) and glutathione reductase (GR)[25]. In previous studies, the induction and/or restoration of these substances and enzymes, which are reduced by ethanol administration, appeared to ameliorate ALD[12,13,23,26]. Some vitamins exhibit antioxidant activity and are reduced in the ALD model[27-29]. They are also deficient in ALD patients, although if present in sufficient quantities, may contribute to the prevention of oxidative stress[30]. Vitamin E is not only a lipophilic antioxidant but also may improve lipid metabolism *via* interaction with lipid accumulation-related proteins, namely patatin-like phospholipase domain containing 3 (PNPLA3) and microsomal triglyceride transfer protein[31]. However, several clinical studies have identified only partial effects of vitamin E in ALD[32,33]. Therefore, the induction of antioxidant enzymes may be more effective than vitamin supplementation in the prevention of ALD.

A trend in gastronomic culture is the exclusion of low molecular weight phytochemicals during plant breeding or processing because of their toxicity, taste, or deteriorating color. However, phytochemicals have recently received attention for their physiological activities in mammals. Many types of phytochemicals abundant in fruit and vegetables are known to have antioxidant activity. Although research efforts have focused on phenolic compounds due to their direct scavenging activity of ROS[34,35], their direct activity towards endogenous ROS appears limited in mammals because of their relatively low concentrations in the bloodstream[2,36,37]. However, many types of polyphenols, non-phenolic phytochemicals, and antioxidant-rich plant fractions have recently been reported to elicit an antioxidant defense system against liver damage induced by ethanol[34,35,38,39], other chemicals[40-43], or abnormal metabolism[21,44] to reduce oxidative stress and cell death[34,42,43,45] and to improve lipid metabolism[12,16,44,46] in various organs. In addition, some phytochemicals change both phase Ⅰ and phase Ⅱ enzymes of drug metabolism, including CYP2E1[7,13,16,47]. Recent reports indicated that some polyphenols can improve epithelial cell junctions[48-51], indicating a role for the hepatic immune response. These findings

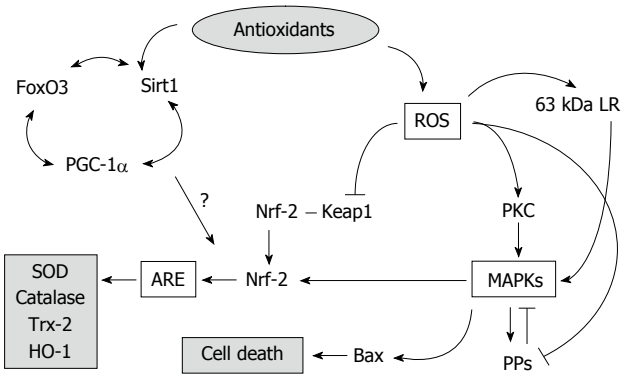

Figure 1 Oxidative stress-stimulating signaling pathways. The oval with the gray indicates the start point; gray boxes indicate consequences; other boxes indicate key substances. ARE: Antioxidant responsive element; FoxO3: Forkhead winged-helix box class O3 transcription factor; HO-1: Heme oxygenase-1; Keap1: Kelch-like ECH-associated protein 1; LR: Laminin receptor; MAPK: Mitogen-activating protein kinase; Nrf2: NF-E2-related factor-2; PGC-1α: Peroxisome proliferator-activated responsive element γ coactivator-1α; PKC: Protein kinase C; PP: Protein phosphatase; ROS: Reactive oxygen species; Sirt1: Sirtuin 1; SOD: Superoxide dismutase; Trx: Thioredoxin.

suggest that phytochemicals could potentially have a comprehensive preventive effect on ALD. However, the physiological activities of phytochemicals in the prevention of ALD have not been well recognized.

In this review, we discuss the physiological activities of phytochemicals and the mechanisms for cell injury, the regulation of antioxidant and pro-oxidant enzyme expression, and concomitant intestinal permeability. Herein, "antioxidants" are defined as the phytochemicals that elicit or enhance the antioxidant defense system, regardless of their radical scavenging activity. Because information regarding the effects of antioxidants in ALD patients or animal models is insufficient for discussion, various oxidative stress models in animals and cells are included. In particular, the mechanisms of non-alcoholic fatty liver disease (NAFLD) may comprise, in part, the mechanisms of ALD because these two diseases likely share many common pathways[31].

MECHANISMS OF LIVER INJURY FROM ALCOHOL CONSUMPTION

As a cause of oxidative stress, ROS are generated by pro-oxidant enzymes, such as CYP2E1 in hepatocytes[7,52,53] and NADPH oxidase (NOX) in Kupffer cells (liver-dwelling macrophages)[25]. In addition, populations of intestinal bacteria that comprise the intestinal environment have been suggested to be involved in ALD *via* stimulation of the immune system. For example, lipopolysaccharides (LPS) derived from intestinal bacteria[15,24,54] activate NOXs and produce inflammatory cytokines[55-58] in macrophages. Acetaldehyde increases the permeability of LPS between intestinal epithelial cells[15,59,60], which is also involved in the deterioration of ALD. Dietary polyunsaturated fatty acids are also thought to enhance oxidative stress[15,29] and are a source of prostaglandins[61]. In a previous study, ethanol administration increased the plasma prostaglandin E_2 level[62], and some prostaglandins are thought to cause inflammation in NAFLD[61,63]. These data suggest that prostaglandins enhance deterioration of ALD; however, the influence of antioxidants on prostaglandins will not be detailed here.

As shown in Figure 1, oxidative stress stimulates intracellular events *via* the mitogen-activating protein kinase (MAPK)[64] pathway, as initiated by the activation of protein kinase C (PKC)[30,65,66] or the degradation of protein phosphatases (PPs)[67]. These signals activate the Kelch-like ECH-associated protein 1 (Keap1)-NF-E2-related factor-2 (Nrf2) pathway, which leads to antioxidant responsive element (ARE)[45,68-70]. However, MAPK hyperactivation also leads to cell death *via* activation of the Bax/Bcl-2 pathway[71,72]. In addition, antioxidant enzymes have been reported to be induced *via* several intracellular pathways, such as the Keap1-Nrf2-ARE pathway[45,69,70,73] and the Sirt1 (sirtuin-1)-FoxO3 (forkhead winged-helix box class O3 transcription factor)-PGC-1a (PPARγ coactivator-1a) pathway[45,68]. The regulation of Sirt1 and Nrf2 levels has also been reported[45], which implies cross-talk between both pathways, whereas the activation of Sirt1 and resveratrol, an activator of Sirt1, have been reported to inhibit the DNA-binding activity of Nrf2 *via* deacetylation *in vitro*[74]. Taken together, substances that deactivate or normalize MAPKs and/or activate ARE or Sirt1[45,75] are potential candidates for the prevention of ALD, but the mechanisms are unknown.

Antioxidant enzymes and peptides

In mammals, SOD generates hydrogen peroxide, which is catabolized to a hydroxyl radical by catalase and detoxified by GSH in collaboration with GPx[25]. The oxidized glutathione form is recruited to GSH by GR with NAD(P)H[76]. Heme oxygenase-1 (HO-1) contributes to the antioxidant system because of the production of bilirubin as a redox substance.

It has been suggested that the hepatic catalase level is negatively associated with the severity of alcoholic liver injury[10] and that SODs scavenge hydroxyl peroxides generated in the cytosol and mitochondria, thereby terminating autoxidation. Thus, catalase and SODs are essential for the antioxidant system. There are three isozymes of SOD in the cytosol, mitochondria, and extracellular matrix: CuZn-SOD, Mn-SOD, and extracellular SOD. SOD levels have been shown to be regulated by MAPK activity[77]. GSH is not an enzyme but a redox tripeptide that acts as a proton donor. GSH levels, GPx content, and/or GR content were reduced in rats fed ethanol diets and, in some cases, ALD animals[16,23,62] or under other oxidative conditions[3,78]. The FoxO transcriptional factor is involved in GPx and Sirt1 protein expression[79]. These findings indicate that in addition to catalase and SOD, GSH is essential for

reducing hepatic oxidative stress.

Under oxidative conditions, HO-1 appears to be rapidly induced *via* the Keap1-Nrf2 pathway[45,69,80,81]. This enzyme may also be involved in the immune response[55]. Furthermore, in ALD model animals, HO-1 levels have been reported to be reduced[13,16,82]. Adiponectin has received recent attention because of its anti-inflammatory functions *via* Sirt1 activation, HO-1 induction, and NOX suppression in Kupffer cells[55]. However, the blood concentration of this adipokine was higher in ALD patients compared with controls[83] or equal to the controls in ALD animals[84], which suggests that adiponectin may be less effective against ALD than antioxidants.

Thioredoxin (Trx) is a ubiquitous scavenger of oxidative species. Endogenous Trx is reported to be reduced by ethanol ingestion; however, the levels can be restored by supplementation with exogenous Trx, which has been demonstrated to ameliorate the symptoms of ALD[84]. Because Trx is a peptide, it must be digested in the digestive system, indicating that it is difficult for exogenous Trx to directly scavenge hepatic ROS.

Pro-oxidant enzymes

In microsomes, CYP2E1 is a phase Ⅰ enzyme of drug metabolism that adds a hydroxyl residue to chemicals to increase hydrophilia and may generate ROS[7-9]. Chronic ingestion of ethanol and other small chemicals increase hepatic CYP2E1. CYP2E1 induction has also been demonstrated in animals with NAFLD[52,85] and hepatic insufficiency. Insulin signaling may suppress CYP2E1 expression[53] *via* the Akt pathway but not the MAPK pathway[86], with subsequent expression of certain microRNAs[87].

Macrophage-like cells, including Kupffer cells, express NOXs and generate ROS with the consumption of NAD(P)H[24] to eliminate xenobiotics[25]. Many isoforms of NOXs have been identified, and NOX-2 is uniquely expressed in phagocytes. NOX expression was regulated *via* the Keap1-Nrf2 pathway in a mouse glial-neural co-cultured system[88] in which NOX-2 predominantly caused oxidative stress. In ALD animals, NOX-2 in Kupffer cells was activated by LPS[55]. In addition, Kupffer cells produce inflammatory cytokines[13,24,55], such as tumor necrosis factor alpha (TNF-α) and interleukin-6. Thus, the reduction of NOXs and inflammatory cytokines are important for ALD.

Given the gut-liver axis in ALD, intestinal conditions play a considerable role in ALD severity, particularly conditions mediated by LPS[15,60]. In the large intestine in humans (or the cecum in animals), an enormous number of intestinal bacteria live and ferment undigested food matter, flaked epithelial cells, and digestive fluid[25]; some of these species generate LPS, which provokes the host's immune system[15]. Small amounts of LPS can pass through gaps in the epithelial cells into the intestine. Ethanol or its metabolites are reported to widen this gap[15,59]. Therefore, improving intercellular junctions or reducing LPS-producing bacteria may have a partial preventive effect on ALD[15].

PLANT ANTIOXIDANTS

Classification of plant antioxidants

Figure 2 shows the structures of representative antioxidants abundant in fruit and vegetables. Polyphenol is a generic name for compounds that have a mono- or polycyclic structure with hydroxyl residues. Flavonoids, including anthocyanins, catechins, and flavonols, form one of the largest groups of polyphenols. Anthocyanins have a red, purple, or blue color in grapes[42], berries[34], seed coats[89], and root crops[37,77]. Catechins include epicatechin, epigallocatechin, and epigallocatechin galate (EGCG) and are sometimes referred to as "tannins"[35]. Proanthocyanidins are polymers of catechins (but not anthocyanin despite the similarity in names); they are categorized as catechins and are widely abundant in crops, particularly tea[27,90], apples[91], and grapes[92]. Quercetin, kaempferol, and isorhamnetin belong to the flavonol group and are ubiquitous in plants. Narirutin and hesperidin belong to the flavanone group and are abundant in the albedo of citrus peel[14,23]. Resveratrol is categorized as a stilbenoid, a phytoalexin, and is present in wine[93] and grapes[42]; it has recently received substantial attention for its physiological functions. Chlorogenic acid is a caffeic acid derivative and one of the most widely consumed polyphenols because of its abundance in coffee and other plants. Alkaloids, such as berberine[46], are also included in the polyphenol group. Curcumin, a curcuminoid present in turmeric, has a yellow color and also belongs to polyphenols.

Lignans, a terpenoid whose metabolites exert estrogenic activity in the lumen, as well as isoflavones and coumestans possess antioxidant activity. Sulfide and thiocyanate compounds are present in garlic[12,82], onions[47], and *Brassicaceae* plants[16] and are reported to be chemopreventive.

PROVOCATION OF THE ANTIOXIDANT SYSTEM BY PLANT ANTIOXIDANTS AND PLANT EXTRACTS

Flavonoids

In animal models, quercetin ameliorated lipid metabolism and ethanol-induced liver damage by inducing antioxidant enzymes, increasing GSH levels, and reducing CYP2E1 activity[20,39]. Quercetin also inhibited the activity and expression of CYP2E1 in human hepatocytes[20,94], which was consistent with *in vivo* findings. In non-alcoholic steatohepatitis animals, quercetin ingestion increased hepatic catalase, SOD, GPx, and GR activities and the GSH level[21] and reduced hepatic lipid accumulation and CYP2E1

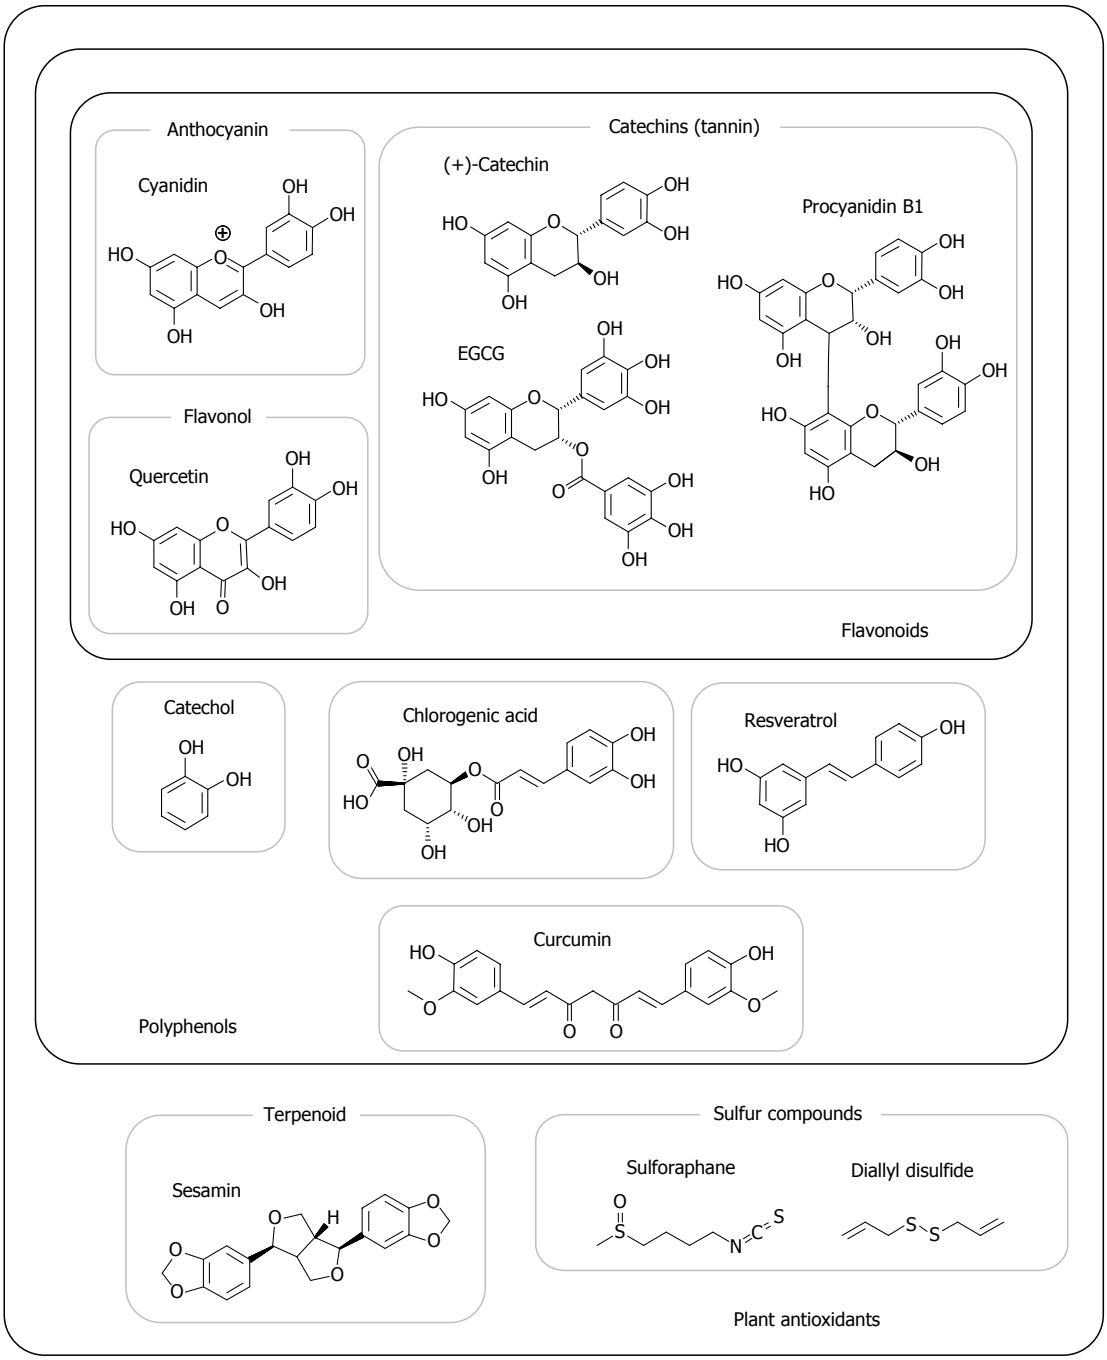

Figure 2 Structures of representative plant antioxidants and their classification.

expression[21,85]. A computer simulation predicted the involvement of quercetin in PGC1a and PNPLA3[31]. Furthermore, hyperoside (quercetin-3-O-galactoside) has been reported to increase cell viability and HO-1 activity *via* MAPKs and ARE[95] in L-02 cells.

Pigments from grapes[42], colored potatoes[77], and black soybean seed coats[89] that contain abundant anthocyanin have been reported to induce antioxidant enzymes *via* the alteration of MAPK activities in cells in other oxidative conditions. An anthocyanin fraction from bilberries appears effective in improving lipid metabolism *via* the AMP-activated protein kinase pathway[96]; however, its involvement in ALD has not been assessed. Alcohol-free red wine increased the blood antioxidant capacity in a human study[97], which suggests a preventive function of the polyphenol fraction in red wine against ALD. However, other studies have demonstrated that alcohol-free red wine worked with ochratoxin A to increase the intercellular permeability in Caco-2/TC7 cells[98], and alcohol-containing red wine increased hepatic and renal CYP2E1 expression in rats, whereas ethanol did not[99]. Malvidin, an anthocyanin in red wine, has been reported to attenuate MAPK activity, which was

promoted by LPS[64], and to enhance PP activity in RAW 264.7 macrophage cells. An anthocyanin-rich extract from colored potato increased Mn-SOD expression *via* extracellular signal regulated kinase (ERK) activation in HepG2 cells[77]. It has also been reported that an ethanol-induced acute gastric lesion was prevented by the ingestion of strawberry extract rich in anthocyanin prior to ethanol treatment *via* the induction of gastric antioxidant enzymes[34].

In animal studies, catechin- and tannin-rich extracts from pecan nut shells improved ALD symptoms by restoring antioxidant enzymes[35,38]. A tea extract rich in catechins reduced CYP2E1 expression and hepatic lesion *via* paracetamol injection[92], and a diet that contained EGCG improved hepatic injury; although there was no reduction in hepatic CYP2E1 levels[100]. In a clinical study, EGCG-rich green tea and its extract also increased the blood GSH level[90]. The ingestion of green tea extract also restored antioxidant activity in the brain that had been decreased by ethanol and aging[28]. Furthermore, catechins have been reported to suppress the expression of NOX and inflammatory cytokines in macrophages[56], dendrocytes[57], and human cerebral microvascular endothelial cells (hCMEC)[101] as well as restore antioxidant enzymes in human neuroblastoma cells[102]. Catechins have both antioxidant and pro-oxidant activities. They have recently been reported to stimulate the 63 kDa laminin receptor[56,57,101,103], which ROS may initiate[104], and consequently to calm over-activation of the immune system *via* the inactivation of the Toll-like receptor (TLR) 2 and 4 pathways. TLR 4, in particular, plays a central role in Kupffer cell stimulation with LPS and the induction of ALD deterioration[57]. Dietary catechins may thus contribute to the impairment of ROS generation *via* LPS and the prevention of ALD.

Citrus flavonoids, narirutin, and glycosylated citrus flavonoids also improved ALD and reduced inflammatory cytokine levels[14,23].

Other phenolic antioxidants and non-phenolic antioxidants

Resveratrol (Figure 2) restores or induces antioxidant enzymes in ALD model rats[93], lung fibroblasts[105], and rats with spontaneous hypertension[75] and diabetes[44,73] *via* the activation of sirtuins in some cases. *In vitro*, resveratrol stimulated HO-1 induction *via* the MAPK-Nrf2 pathway in PC12 cells[81]. Thus, red wine consumption is likely to be superior to other alcoholic beverages in the prevention of ALD. Resveratrol concentrations in wine may be insufficient to prevent ALD; however, it may be responsible for the "French paradox"[106]. Resveratrol has been reported to activate monocytes and produce inflammatory cytokines *in vitro*, which indicates that provoking the immune system with resveratrol may not prevent the deterioration of ALD[107]. Thus, excessive red wine consumption should not be recommended. Polydatin, a resveratrol glycoside, stimulates Sirt1 and Nrf2 and induces antioxidant enzymes in glomerular cells[45].

Chlorogenic acid (Figure 2) and caffeic acid restored the hepatic activity of SOD and GPx and hepatic injuries promoted by methamphetamine injection for 7 d[43].

Honokiol, identified in *Magnolia officinalis*[19], improved ALD, restored the hepatic GSH content and SOD activity, and reduced inflammatory cytokine levels in an ALD animal model[19].

Hispidin, a fungal polyphenol with PKC-inhibitory activity, increased HO-1 and catalase activities in H9c2 cardiomyoblast cells[65].

Berberine is a benzyl isoquinoline alkaloid in the *Coptis* genus that has been reported to reduce ALD symptoms, increase levels of GSH and PGC1a, and normalize CYP2E1 expression in the livers of animals fed an alcohol-containing diet[46].

The sulfur-containing compounds (Figure 2) diallyl disulfide and garlic oil have been reported to improve alcoholic hepatic injury[12] by increasing HO-1 levels *via* the Nrf2 pathway and increasing the GSH level *in vivo*[82] and *in vitro*[94]. A similar preventive effect has also been identified in diallyl sulfide treatment in astrocytes[30]. Sulforaphane has been reported to act as an inducer of HO-1[16], which suggests that these compounds may be useful in the treatment of ALD. In addition to restoring HO-1 levels, sulforaphane improved hepatic lipid accumulation in ALD animals[16]. The consumption of onion powder, which is rich in sulfide compounds and flavonols, has also been reported to reduce hepatic CYP2E1 levels in normal rats[47].

Oleanolic acid, a triterpenoid, restored antioxidant enzymes and increased nucleic Nrf2 levels and improved ALD[13]. Sesamin (Figure 2) is a well-characterized terpenoid in sesame seeds that may contribute to the reduction of fatty liver by promoting β-oxidation of fatty acids and inducing hepatic aldehyde dehydrogenase[108,109]. Maslinic acid, a triterpenoid rich in basil, brown mustard, and other plants, has been reported to protect hepatic injury *via* acute ethanol toxicity[62]. These data suggest that some types of terpenoids may improve the symptoms of ALD.

Curcumin (Figure 2), but not resveratrol, has been reported to restore hepatic antioxidant enzymes reduced by aflatoxin in rats[110]. Curcumin also increased antioxidant enzymes as well as Nrf2 and HO-1 levels in quails under heat stress[111].

Mangiferin, identified in mango[112], is a xanthine derivative that has been reported to restore pulmonic and hepatic antioxidant enzyme levels reduced by benzo(a)pyrene in mice[3].

Plant extracts that contain significant amounts of antioxidants also prevent oxidative damage in various other organs. An extract from black tea[27] improved ALD symptoms in rats. The extracts from apples[91], *Amorphophallus commutatus*[40], cinnamon[113], and hibiscus[22,41] partially normalized hepatic oxidative

stress induced by chemical toxins.

Improvement of fatty acid accumulation

Alcoholic fatty liver is a predictive symptom of ALD, and hepatic inflammation is also present in non-alcohol steatohepatitic animals[21,41,52]. Moreover, a computer simulation predicted many common pathways between alcoholic fatty liver and NAFLD that were associated with inflammation, lipid metabolism, and some immunity[31]. These data suggest that a reduction in lipids in the liver may lead to an improvement in liver injuries[16,19,100]. In addition to the induction of antioxidant enzymes, some plant antioxidants have recently been reported to improve lipid metabolism and reduce hepatic lipid accumulation[19,39,46], which may also contribute to the amelioration of ALD.

Improvement of intestinal permeability by plant antioxidants and plant extracts

Antioxidants, such as quercetin, resveratrol, EGCG, and naringenin, prevent the downregulation of junction proteins, namely, Zo-1 and/or Occludins, and consequently enhance intercellular barrier functions *in vitro*[49] and *in vivo*[50]. In contrast, EGCG has been reported to disturb the barrier function of hepatic epithelial cells[114] because of ROS-induced ERK activation. In addition to intestinal cell models, cocoa polyphenol extract improved barrier functions disturbed by a high glucose condition in retinal pigment epithelium cells[51]. Cocoa polyphenol extract and resveratrol also attenuated the permeability of renal cell junctions *in vitro*[48,115], and EGCG increased the adhesion of hCMEC[101]. The tightness of cellular junctions regulated by antioxidants may be involved in the severity of ALD and should be elucidated.

Mechanisms for ALD prevention via plant antioxidants

Cellular oxidative stress is caused by many factors, such as exposure to humoral factors[22,75], enzymatic generation of ROS[7-9,24], metabolites of chemicals[41,91,102,116], or the mitochondrial respiratory chain[39]. Two major mechanisms may be proposed for hepatic injury prevention *via* oxidation: (1) the impairment of oxidative signaling that leads to cell death; and (2) the activation of the Keap1-Nrf2 pathway, which results in the induction of antioxidant enzymes.

As a leading mechanism, "preconditioning" in ischemia-reperfusion models has been proposed to alleviate tissue damage. In ischemia-reperfusion models, excessive ROS are present following reperfusion, whereas slight ischemic-reperfusion pretreatment to tissues or cells alters MAPK activities and interferes with cellular damage[117-119]. It has been reported that ROS stimulate PKC, MAPKs, and subsequent events that lead to cell death[89] or induce an antioxidant system (Figure 1). MAPKs appear to activate both PPs[66,120] and Nrf2[69]. Once activated, PPs may deactivate not only MAPKs but also other phosphorylated proteins related to the MAPK signaling pathways[66], which may lead to a comprehensive impairment of MAPK signaling. Despite their antioxidant activity, polyphenols also have a slight pro-oxidant activity[72,121]. This impact may increase MAPK and PP activity[103] or PP stability[120] prior to crucial oxidative stress by ROS. At minimum, PPs activated by antioxidants may partially inhibit MAPK pathway activation. Following pretreatment with plant antioxidants, the hyperactivation of MAPKs by injuring stimuli appears to decrease[22,41,48,64]. These findings may support the preconditioning hypothesis[1]. Taken together, ROS and/or MAPK are key regulators of both cell injury and antioxidant enzyme induction.

In addition, this mechanism can explain the effects of antioxidants on the barrier functions of epithelial cells. Junction proteins and the intercellular barrier function are disturbed by oxidative stress[48,114]. Antioxidants have been reported to exhibit minimal activity to generate ROS[114,121] and subsequently activate MAPKs, which disturbs barrier function *in vitro*[114]. However, antioxidant pretreatment may diminish excessive oxidative stress, as previously discussed, which leads to the protection of barrier function[49,50].

It has been suggested that ROS (and electrophilic reagents) directly activate the Keap1-Nrf2 pathway. Keap1 is a sensor of intracellular oxidative stress and couples with Nrf2[122]. Once Keap1 is oxidized, Nrf2 is released, moves to the nuclei, and activates ARE. Regarding the relationship between chemical structures and antioxidant activities, it has been suggested that electrophilic compounds, such as flavonoids, curcumin, and thiocyanate-related compounds, stimulate the Keap1-Nrf2 pathway[122]. Satoh *et al*[123] proposed the importance of ortho- or para-positions of hydroxyl residues in the benzene structure, which result in hydroquinone and catechol, respectively (Figure 2), because of their electrophilic residue. Some flavonoid compounds have a catechol structure (Figure 2), which indicates an interaction between flavonoids and Keap1. These results may support the hypothesis proposed by Satoh *et al*[123].

This hypothesis suggests that antioxidants directly activate Keap1. However, some antioxidants appear to induce antioxidant enzymes *via* MAPK activation despite the upper proteins of Keap1 (Figure 1), as demonstrated with specific inhibitors of MAPKs that diminished the induction[77] or activation of Nrf2[81]. Antioxidants may contribute to the induction of antioxidant enzymes *via* MAPK pathways rather than through direct activation of Keap1. Moreover, resveratrol has a resorcinol structure rather than a catechol structure. Resorcinol has less electrophilic activity than catechol[123]; however, it appears to stimulate Nrf2[122]. This mechanism must also be elucidated.

In *in vivo* studies, the ingestion of antioxidants induces (or tends to induce) antioxidant enzymes in the lung[3], thymus[124], brain[28,125], and kidney[45], despite very low concentrations in the bloodstream[2,36,37].

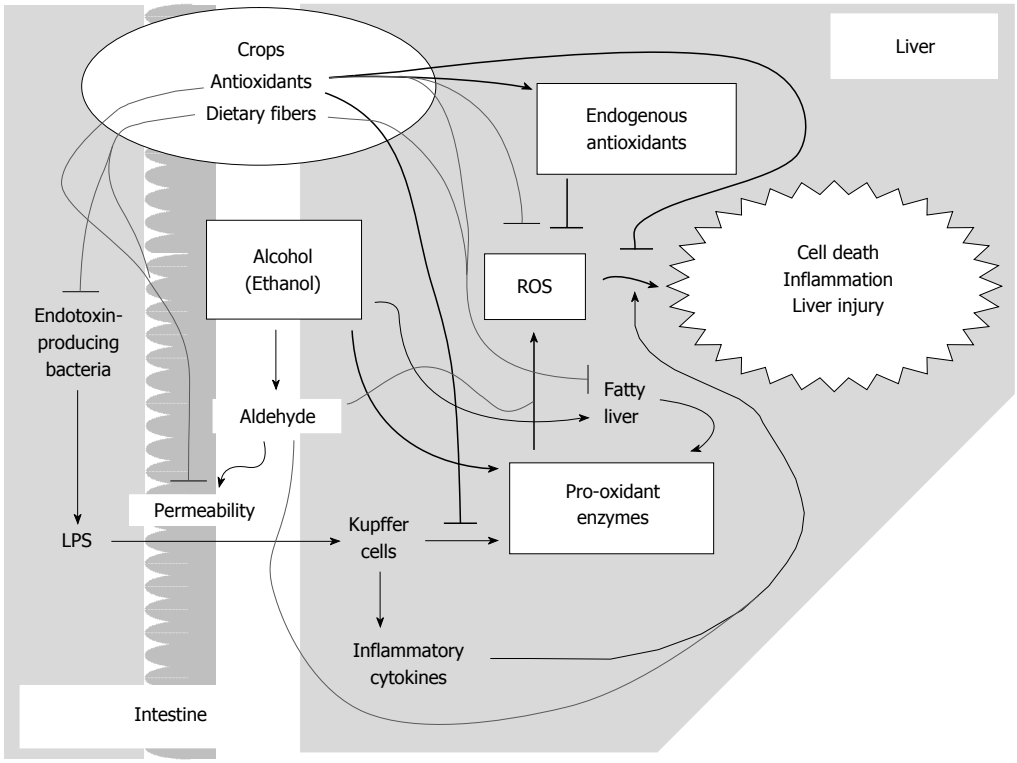

Figure 3 Potential multiple effects of crop components on alcoholic liver disease. LPS: Lipopolysaccharide; ROS: Reactive oxygen species.

These reports imply that there is an intermediate signal by polyphenols, such as nerve and/or humoral pathways, rather than direct stimulation of cells or organs; they may also be explained by remote ischemic preconditioning[117]. This preconditioning suggests that some types of stimuli can regulate MAPK activities in remote organs.

PERSPECTIVE

Even ubiquitous plant antioxidants, such as anthocyanins and flavonols, appear to have many physiological activities, indicating that botanical substances can provoke the antioxidant system. Apart from oxidative stress *via* lipid accumulation, lipids also appear to be a central cause of ALD. For example, prostaglandins, which are initiated by phospholipase (PL) A_2 and activated by cyclooxygenases[61], are involved in inflammatory events, and PNPLA3 has been suggested to have PLA_2 activity and to regulate hepatic lipid accumulation[63]. Therefore, the regulation of prostaglandins and/or expression of their related proteins may be critical for the improvement of ALD.

Fruits and vegetables are great sources of antioxidants as well as dietary fibers (DFs)[126], which were once considered to be unwanted materials or non-nutrients. It is now well established that the ingestion of DFs improves lipid metabolism and reduces hepatic lipids[127,128]. Some types of DFs, particularly water-soluble fibers, promote the excretion of lipids into feces and the synthesis of short-chain fatty acids (SCFA) in the intestine[126,129], which are proposed as prebiotics. Oral ingestion of butyrate, a type of SCFA produced from DF, promotes junction protein expression and an increase in intestinal barrier function[130]. These findings also suggest the potential of DFs in the prevention of ALD. Thus, intact fruits and vegetables, including both antioxidants and DF, are worthy of consideration for ALD prevention.

Mammals often intrinsically treat plant chemicals as xenobiotics and have developed metabolic systems against phytochemicals[1]. The human body evolved with environmental factors, including phytochemicals and DFs. The data reviewed here imply the necessity for the unwanted materials to elicit an accomplished defense system, a barrier function in the intestine and a chemical metabolizing system in the intestine, and liver against xenobiotic substances.

However, most of these data are derived from animal and cell studies. In these studies, antioxidants may, in some cases, be overdosed[75], which makes it difficult to justify their effectiveness in humans, particularly ALD patients who may have impaired liver functions[11]. As previously reported, vitamin E supplementation only partially improved ALD[32,33] despite its effectiveness in cell studies. Thus, it is important for future studies to accumulate clinical data regarding the relationships among ALD, antioxidants, and antioxidant enzymes.

In conclusion, plants have a potential role in the prevention of ALD (Figure 3). Although most individuals are aware that abstinence from alcohol is the most

effective way to prevent ALD, it is recognized that this is not easy. Therefore, it is important to improve our defense system against ALD. Many types of plant antioxidants with electrophilic activity may activate antioxidant enzymes or peptides under oxidative conditions and alleviate ALD, which may occur *via* a mechanism that is somewhat similar to preconditioning in ischemia-reperfusion models[117-119]. The antioxidants reviewed here are common in vegetables and fruits, which can be easily consumed. Moreover, plants contain abundant amounts of DF and vitamins. Vitamins are wasted by binge drinking[27,28], and DFs can improve lipid metabolism and intestinal conditions[127,128] in mammals. Therefore, non-processed food materials may have considerable intrinsic potential. Clearly, ALD patients should be administered appropriate medications to facilitate recovery from crucial damage. However, fresh vegetables and fruits may be more effective than processed foods in comprehensively preventing hepatic damage induced by alcohol. Antioxidants commonly taste bitter, and DFs appear to exhibit a bad texture; thus, they have been eliminated from foods over centuries. However, humans have evolved alongside phytochemicals and DFs to overcome these issues. Thus, an approach that elicits the intrinsic potential of the human body to prevent ALD and other lifestyle-related disorders should be reconsidered.

Chapter 22
Transgenic Mouse Models for Alcohol Metabolism, Toxicity, and Cancer

Claire Heit, Hongbin Dong, Ying Chen, Yatrik M. Shah, David C. Thompson, and Vasilis Vasiliou

Abstract Alcohol abuse leads to tissue damage including a variety of cancers; however, the molecular mechanisms by which this damage occurs remain to be fully understood. The primary enzymes involved in ethanol metabolism include alcohol dehydrogenase (ADH), cytochrome P450 isoform 2E1, (CYP2E1), catalase (CAT), and aldehyde dehydrogenases (ALDH). Genetic polymorphisms in human genes encoding these enzymes are associated with increased risks of alcohol-related tissue damage, as well as differences in alcohol consumption and dependence. Oxidative stress resulting from ethanol oxidation is one established pathogenic event in alcohol-induced toxicity. Ethanol metabolism generates free radicals, such as reactive oxygen species (ROS) and reactive nitrogen species (RNS), and has been associated with diminished glutathione (GSH) levels as well as changes in other antioxidant mechanisms. In addition, the formation of protein and DNA adducts associated with the accumulation of ethanol-derived aldehydes can adversely affect critical biological functions and thereby promote cellular and tissue pathology. Animal models have proven to be valuable tools for investigating mechanisms underlying pathogenesis caused by alcohol. In this review, we provide a brief discussion on several animal models with genetic defects in alcohol-metabolizing enzymes and GSH-synthesizing enzymes and their relevance to alcohol research.

22.1 Introduction

The Centers for Disease Control and Prevention reported that the annual number of alcohol-related deaths was 88,000 in the United States from 2006 to 2010. Alcohol is a causal factor in more than 60 human diseases and places a significant burden on the economy with healthcare costs estimated in 2006 as surpassing 223 billion dollars in the United States alone [1]. A comprehensive understanding of the mechanisms mediating alcohol toxicity is essential because it facilitates the development of therapies that prevent and/or treat the pathologies associated with alcohol consumption. The cellular and molecular mechanisms leading to alcohol-induced tissue damage are not fully understood. However, emerging evidence indicates that common mechanisms of cell injury, such as stress, inflammation, and alterations in signaling (including apoptosis) pathways, are all involved in the deleterious effects of alcohol.

Animals in which expression of specific proteins are repressed, the so-called knockout animals, represent an innovative and powerful research tool for scientific discovery. Genetic manipulation of proteins involved in the metabolism of ethanol or in the cellular defense mechanisms against alcohol-induced oxidative stress have allowed the exploration of their roles in alcohol-related pathologies, such as alcoholic liver disease, pancreatitis, cardiovascular disease, and diabetes mellitus, as well as in various cancers, including oral, colorectal, liver, pancreatic, aerodigestive, breast, and colon [2–7]. Currently available animal models will be outlined in the following review. In addition, double and triple knockout strains of these mice are currently being produced in our laboratory.

22.2 Clinical Significance of Human Polymorphisms of Genes Involved in Ethanol Metabolism

Ethanol is metabolized primarily *via* oxidation to acetaldehyde through the enzymatic activity of alcohol dehydrogenases (ADH), catalase (CAT), and cytochrome p450 2E1 (CYP2E1) (Fig. 22.1). Acetaldehyde is then oxidized to acetate by the aldehyde dehydrogenases (ALDHs). The role of ADH in ethanol metabolism is well established [8–10]. The human genome contains three Class I *ADH* genes (*ADH1A, ADH1B, ADH1C*); in contrast, rodents have only one *Adh1* gene [11]. Genetic polymorphisms in *ADH1* genes are associated with colon and breast cancers [4, 5, 12]. The role of CYP2E1 in ethanol metabolism, oxidative injury, and cancer is also well established [13–17] and genetic polymorphisms are associated with increased cancer risk [18–20]. Catalase appears to play an important role in ethanol metabolism in the brain [14, 15]. Nevertheless, polymorphisms in the catalase gene are associated with diabetes mellitus, hypertension, and vitiligo [21, 22]. ALDHs are a family of 19 human proteins that metabolize aldehydes, in which three isoforms are responsible for metabolizing acetaldehyde. Mitochondrial ALDH2 is the primary enzyme involved in the metabolism of acetaldehyde ($Km \leq 5$ μM). The ALDH2*2 allele

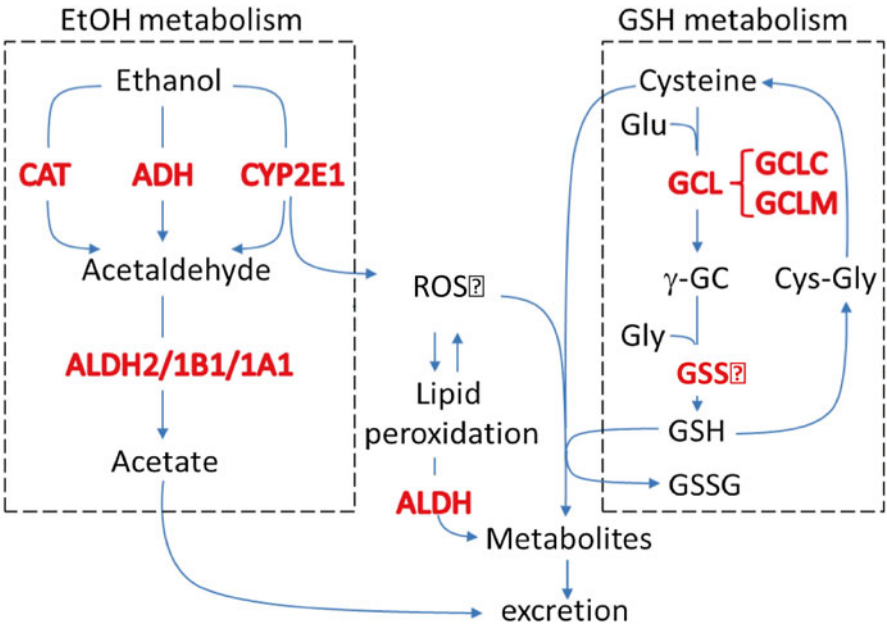

Fig. 22.1 Major enzymatic pathways involved in ethanol and glutathione metabolism. Ethanol (EtOH) is subject to metabolism by catalase (CAT), cytochrome P450 isoform 2E1 (CYP2E1), and alcohol dehydrogenase (ADH). Acetaldehyde is metabolized by aldehyde dehydrogenase (ALDH) isoforms 1A1, 1B1, and 2. In the glutathione (GSH) pathway, glutamate cysteine ligase (GCL), which includes two subunits the catalytic subunit (GCLC) and the modifier subunit (GCLM), catalyzes the synthesis of γ-glutamylcysteine (γ-GC). γ-GC is then coupled to glycine by glutathione synthetase (GSS) to form GSH. During oxidative processes, reactive oxygen species (ROS) form which can cause lipid peroxidation. ROS can be reduced by GSH, in the process forming GSSG, the oxidized form

(which appears restricted to an Asian genetic background) causes marked reductions in acetaldehyde metabolism that manifest clinically as flushing syndrome and ethanol avoidance in heterozygous and homozygous individuals. This polymorphism is also associated with alcohol-related cancers [3, 23]. ALDH1B1 has the next lowest Km for acetaldehyde (Km = 55 μM), implicating a role in acetaldehyde metabolism secondary to ALDH2. ALDH1B1 has been proposed as a biomarker for colon cancer [24]. Several ALDH1B1 polymorphisms have been found in humans and recent studies have linked these polymorphisms to drinking aversion, elevated systolic blood pressure, and frequent hypersensitivity reactions in Caucasians [25, 26]. ALDH1A1 has a role in acetaldehyde metabolism and drinking preference [27, 28] and a deficiency in this enzyme is associated with ethanol hypersensitivity in Caucasian subjects [29]. Polymorphisms in alcohol- and acetaldehyde-metabolizing enzymes have been closely linked with alcohol-related cancers. In a Japanese population, p53 accumulation, esophageal neoplasia, and esophageal squamous cell carcinomas were increased in subjects whose genes included the inactive heterozygous allele ALDH2 *1/*2 and the less active ADH1B *1/*1 [30, 31]. These polymorphisms also exhibited more frequent acetaldehyde-induced DNA damage [32].

Taken together, the association between human polymorphisms of ethanol-metabolizing genes and alcohol-related diseases implicates a significant pathogenic role of ethanol metabolism in alcohol toxicity. Various research groups have developed animal models that harbor genetic ablations of ethanol-metabolizing enzymes. These models can serve as important experimental tools to elucidate the mechanistic roles of specific enzymes or pathways in alcohol-related diseases and therefore have direct relevance to alcohol research.

22.3 Animal Models for Alcohol-Induced Cancer

Low to moderate consumption of alcohol has tissue-protective properties [33]. However, heavy alcohol consumption increases the risk of several diseases, including cancer. A comprehensive review of epidemiological data demonstrated a significant increase in cancer risk for several epithelial-derived tumors associated with ethanol consumption [3]. Studies using experimental animals, however, support the notion that ethanol acts as a cocarcinogen or tumor promoter rather than being a carcinogen itself [5]. The mechanisms by which alcohol promotes tumorigenesis remain unclear due primarily to a lack of good animal models that can recapitulate the increased risk of alcohol in carcinogenesis. Animal models analogous to inflammation-promoted cancers, such as the azoxymethane (AOM)/dextran sulfate sodium (DSS) model, are needed [34]. In this model, the carcinogen AOM by itself is administered at a dose that causes no dysplasia; however, when administered in combination with DSS (which induces inflammation), a synergistic increase in the number of tumors is observed. The creation of a similar model for alcohol will rely on a better understanding of the interactions between the genetic mutations (or carcinogen) with the duration, route, and concentration of ethanol for the epithelial tumor that is to be modeled. Moreover, diets that better mimic heavy alcohol consumption in humans are required. The interaction of tumor-promoting dietary components, such as alcohol, high-fat, and iron, may lead to more robust and precise models. Lastly, experimental evidence indicates that the metabolism of ethanol leading to the generation of acetaldehyde and free radicals is intimately involved in alcohol-associated carcinogenesis [3]. Therefore, a more comprehensive understanding of the enzymes required for alcohol metabolism in cancer are needed and the genetic animal models discussed in this review could represent unique opportunities to identify their roles in alcohol-induced cancers.

22.4 Glutathione in Alcoholic Tissue Injury

In the development of alcohol-induced tissue injury, it is apparent that numerous pathways in target organs are modulated by ethanol [35, 36]. Oxidative stress appears to play a central role in many of these pathways [37]. Ethanol metabolism, CYP2E1

induction, compromised antioxidant defense, mitochondrial injury, inflammation, hypoxia, and iron overload can all contribute to the alcohol-induced oxidative environment. Accumulation of the reactive molecules (including reactive oxygen species and electrophilic products, such as acetaldehyde and lipid peroxidation products) can be harmful to a biological system due to their propensity to inactivate enzymes and cause DNA damage, loss of protein functions and cell death [38].

Glutathione (GSH) plays an important role as an antioxidant by serving as a cofactor for antioxidant enzymes, such as glutathione peroxidase and glutathione *S*-transferases, or by directly scavenging free radicals [39]. It is the most abundant nonprotein thiol, attaining a concentration in the high millimolar range in the liver [40]. Because of its abundance, GSH plays a key role in maintaining cellular redox homeostasis and, therefore, enzymes that help generate GSH are critical in protecting cells against oxidative stress. GSH is a tripeptide composed of glutamate, cysteine, and glycine. It is synthesized in most types of cells by two successive enzymatic reactions. The first reaction couples glutamate and cysteine and is catalyzed by glutamate-cysteine ligase (GCL), resulting in the formation of γ-glutamylcysteine (γ-GC) [41] (Fig. 22.1). The second reaction, catalyzed by GSH synthetase, couples γ-GC with glycine. The formation of γ-GC by GCL is considered rate-limiting in GSH biosynthesis, and GCL has been the principal target of drugs designed to inhibit GSH biosynthesis [41] and to generate mice with GSH deficiency [42].

In higher eukaryotes, GCL in its most catalytically efficient form is a heterodimer composed of a catalytic (GCLC) and a modifier (GCLM) subunit, each of which is encoded by separate genes on different chromosomes. GCLC possesses all of the catalytic activity of γ-GC formation; GCLM optimizes the kinetic properties of the holoenzyme, thereby regulating tissue GSH levels [43]. GSH is exclusively synthesized in the cytoplasm [39] and further distributed into mitochondria, endoplasmic reticulum, and nuclei, where it plays a pivotal role in the normal functioning of these subcellular organelles [44]. During detoxication of free radicals, GSH is oxidized to glutathione disulfide (GSSG). Both GSH and GSSG can be transported outside the cell where it is broken down in sequence by γ-glutamyl transferases and dipeptidase, producing free cysteine and glycine for intracellular reutilization [45]. Depletion of hepatic GSH, particularly mitochondrial GSH, occurs as a result of excessive GSH consumption by free radicals and acetaldehyde generated during alcohol metabolism [46]. Given the above considerations, animal models exhibiting a GSH deficiency will serve as important tools to study GSH-regulated redox biology in ethanol metabolism and ethanol-induced tissue damage. As such, they are of direct relevance to alcohol research.

22.5 Mouse Models with Genetic Deficiencies in Ethanol-Metabolizing Enzymes

ADH1 global knockout: The *Adh1*$^{-/-}$ mouse line has been generated by Duester [47] (Table 22.1). It should be noted that human *ADH1* gene family consists of three genes, *viz. ADH1A*, *ADH1B*, and *ADH1C*, whereas the mouse genome has a single

Table 22.1 Transgenic mouse models

Strain	Genetic background	Phenotype	References
Adh1$^{-/-}$	C57BL6	• No gross abnormality • Reduction in blood ethanol clearance	Deltour et al. [9]
Cat$^{-/-}$	C57BL6	• No gross abnormality • Deficiency in brain mitochondrial respiration • Has not been used in ethanol toxicity studies	Ho et al. [49]
Cyp2e1$^{-/-}$	129/Sv	• No gross abnormality • Decreased sensitivity to acetaminophen hepatotoxicity • Resistance to ethanol-induced fatty liver and oxidant stress	Lee et al. [50], Lu et al. [54]
Cat$^{-/-}$ *Cyp2e1*$^{-/-}$ *double knockout*	C57BL6/129 mixed	• No gross abnormality • Has not been used in ethanol toxicity studies	Unpublished
Aldh2$^{-/-}$	C57BL6	• No gross abnormality • High susceptibility to ethanol toxicities by oral administration • High sensitivity to inhalation toxicities of acetaldehyde	Isse et al. [55], Oyama et al. [59, 61]
Aldh1a1$^{-/-}$	C57BL6	• Viable and fertile • Decreased susceptibility to diet-induced obesity and insulin resistance • Cataract development at age of 6-month • Has not been used in ethanol toxicity studies	Fan et al. [74], Ziouzenkova et al. (2007)
Aldh1b1$^{-/-}$	C57BL6	• No gross abnormality • Reduction in blood acetaldehyde clearance	Unpublished

A variety of transgenic strains are available for research. For each strain, the genetic background and phenotypes are provided

Adh1 gene [11]. *Adh1*$^{-/-}$ *mice* have limited capacity to oxidize ethanol and retinol. Pharmacokinetic studies show a reduction in blood ethanol clearance in these animals [9]. Following parenteral administration of ethanol, these mice displayed an increased sleep time and embryonic resorption was increased threefold [9]. While ADH1 is thought to be responsible for the majority of ethanol metabolism in the liver, new pharmacokinetic evidence suggests a role for other ADH isoforms as well [48]. Therefore, this model may be useful in determining the pathophysiological importance of compensatory ADH isoforms as well as elucidating the kinetics of these enzymes for ethanol.

Catalase global knockout: The *Cat*$^{-/-}$ mouse strain was developed and characterized by Ho and colleagues [49] (Table 22.1). These mice do not express catalase and

develop normally, i.e., exhibit no gross abnormalities. However, brain mitochondria of these animals show deficiencies in mitochondrial respiration. To date, this knockout strain has not been subjected to ethanol toxicity studies. Given that earlier studies have shown a significant role of catalase in modulating ethanol sensitivity in the brain [14, 15], the *Cat*$^{-/-}$ mice would be anticipated to be a valuable animal model for examining ethanol drinking preference as well as alcohol toxicities.

CYP2E1 global knockout: CYP2E1 is an ethanol-inducible enzyme with a role in hepatic ethanol oxidation. By genetically ablating exon 2 of *Cyp2e1* gene, Gonzalez and colleagues developed *Cyp2e1*$^{-/-}$ mice [50] (Table 22.1). These mice do not express CYP2E1 enzyme and develop normally [50]. They also show lower sensitivity to the deleterious hepatic effects of acetaminophen [50]. As one of the primary xenobiotic/endobiotic-metabolizing p450s, CYP2E1 is a contributor to a variety of cellular toxicities induced by endogenous or exogenous pathogens. Using the *Cyp2e1*$^{-/-}$ mouse model, CYP2E1 has been shown to play a pivotal role in mediating hepatotoxicity making this an interesting model for alcohol-related liver toxicity [51, 52] *Cyp2e1*$^{-/-}$ and *Cyp2e1* knock-in mice have been used to examine the potentiation of ethanol-induced hypoxia. *Cyp2e1*$^{-/-}$ mice exhibited the lowest levels of hypoxia and HIF1-α [53]. Similarly, ethanol-induced fatty liver and oxidant stress are blunted in these mice [54]; this study confirmed the important role of CYP2E1 in ethanol-induced liver toxicities. *Cyp2e1*$^{-/-}$ mice also display longer ethanol-induced sleep time than do wild-type mice [15], confirming the relevance of the *Cyp2e1*$^{-/-}$ mouse line for the study of the CYP2E1 enzyme in ethanol toxicities and alcohol-induced drinking preference.

22.6 Mouse Models with Genetic Deficiencies in Acetaldehyde-Metabolizing Enzymes

ALDH2 global knockout: The *Aldh2*$^{-/-}$ strain was originally developed and characterized by Isse and colleagues [55, 56] (Table 22.1). *Aldh2*$^{-/-}$ mice do not express ALDH2 protein and have no detectable capacity to oxidize acetaldehyde, propionaldehyde, or methoxyacetaldehyde in liver mitochondrial fractions. Following oral administration of ethanol, *Aldh2*$^{-/-}$ mice exhibit higher ethanol and acetaldehyde levels and lower acetate levels in the blood, brain, and liver than *Aldh2*$^{+/+}$ mice [57, 58]. Further, they are more susceptible to ethanol-induced body weight loss [59], but show no change in mortality [60]. *Aldh2*$^{-/-}$ mice are more sensitive to the toxic effects of inhaled acetaldehyde [61] and exhibit more frequent mutations in the T cell receptor site than their corresponding wild-type [62]. A single oral dose of ethanol in *Aldh2*$^{-/-}$ downregulates the alcohol-metabolizing CYP2E1 mRNA [63], which suggests that there is compensation due to an abundance of acetaldehyde. This treatment has also been shown to decrease hepatic malondialdehyde and increase hepatic glutathione, both markers of oxidative stress, in *Aldh2*$^{-/-}$ mice [64]. Acetaldehyde adducts are also increased in *Aldh2*$^{-/-}$ mice. These mice have been

used to determine ethanol- and acetaldehyde-induced cholinergic changes in the hippocampus. The null mice exhibit decreases in choline acetyltransferase mRNA and protein; however, neurotrophins (nerve growth factor or brain-derived neurotrophic factor) remain unaffected [65], indicating that aldehydes have a selective effect in the brain. *Aldh2*$^{-/-}$ mice also exhibit alcohol avoidance in a test of preference and difference in liver or brain acetaldehyde levels [55]. ALDH2 also appears to influence bone growth and cardiac function, as demonstrated by reductions in trabecular bone formation and cardiomyocyte function in *Aldh2*$^{-/-}$ mice treated with alcohol [66, 67]. Stomach DNA adducts are dramatically increased after chronic ethanol feeding of *Aldh2*$^{-/-}$ mice [68, 69] and acute ethanol treatment increases hepatic oxidative DNA adducts in null mice [70, 71]. The *Aldh2*$^{-/-}$ strain represents a valuable strain that can be used to identify functions of ALDH2 in ethanol metabolism and toxicity.

ALDH2 conditional knockout: A "knockout-first" conditional allele for *Aldh2* has been developed by Skarnes and colleagues [72]. These mice have been crossed with *FLP* mice to generate *Aldh2* floxed conditional knockout (*Aldh2*$^{f/f}$) mice, which can be further crossed with specific *CRE* mouse lines to generate cell-specific *Aldh2* knockout mice. As expected, *Aldh2*$^{f/f}$ mice develop normally and exhibit no observed phenotype (unpublished observation). To date, no ethanol studies have been conducted in these mice. This strain can be used to study tissue-specific contributions of ALDH2 in ethanol metabolism and toxicity.

ALDH1B1 global knockout: The *Aldh1b1*$^{-/-}$ strain was recently generated by Vasiliou and coworkers (*Singh S, Vasiliou V et al.*, manuscript in preparation) (Table 22.1). The *Aldh1b1*$^{-/-}$ mice develop normally and show no overt phenotype. In agreement with the catalytic properties of ALDH1B1 (i.e., the second lowest Km for acetaldehyde oxidation [73]), these mice exhibit higher blood concentrations of acetaldehyde following acute ethanol administration [manuscript in preparation]. The *Aldh1b1*$^{-/-}$ strain represents the first animal model for the study of ALDH1B1 enzyme in ethanol-induced tissue injury.

ALDH1A1 global knockout: The *Aldh1a1*$^{-/-}$ mouse line has been generated by Fan et al. [74] (Table 22.1). These mice are fertile and exhibit no overt phenotype, except that aged *Aldh1a1*$^{-/-}$ mice display ~2.4-fold higher cataract incidence than wild-type mice [75]. While ALDH1A1 primarily metabolizes retinaldehyde, it also plays a role in acetaldehyde metabolism. Genetic variants of *ALDH1A1* (that result in low enzyme activity) have been associated with increased alcohol sensitivity in Caucasians [29]. Therefore, the *Aldh1a1*$^{-/-}$ mouse line represents a useful animal model for investigation of the ALDH1A1 enzyme in ethanol toxicities.

22.7 Mouse Models with GSH Deficiency

GCLC conditional (Gclc $^{f/f}$*) knockout*: The global gene knockout of *Gclc* results in embryonic lethality, indicating an essential role of GSH in mouse development [76]. The *Gclc*$^{f/f}$ strain was developed and originally characterized by Chen and

colleagues [77]. The in vivo role of hepatic GSH has been investigated using the hepatocyte-specific *Gclc* knockout ($Gclc^{h/h}$) mice created by intercrossing $Gclc^{f/f}$ and *Alb-Cre* mice [77]. $Gclc^{h/h}$ mice experience almost complete loss of hepatic GSH (~5 % of normal) and die from acute liver failure when mitochondrial failure occurs [77]. Chronic administration of *N*-acetylcysteine, a treatment that promotes only a mild increase in liver GSH levels (to 8 % of normal) but partially preserves mitochondrial function, allows $Gclc^{h/h}$ mice to survive to adulthood, albeit with the serious liver pathologies fibrosis and cirrhosis [78]. These studies demonstrate an essential role of GSH in normal functioning of the liver. The $Gclc^{f/f}$ mice represent a unique model that can be used to elucidate cell-specific functions of GSH in ethanol metabolism and toxicity.

GCLM global knockout: The $Gclm^{-/-}$ strain was developed and originally characterized by Yang and coworkers [79]. $Gclm^{-/-}$ mice are viable and fertile, despite having only 9–16 % of the normal GSH levels in liver, lung, pancreas, erythrocytes, and plasma [79]. Except when challenged with oxidant stress [80, 81], $Gclm^{-/-}$ mice exhibit no overt phenotype, making them a useful model for studying chronic GSH depletion. Interestingly, these mice show accelerated clearance of ethanol and acetaldehyde and are protected from alcohol-induced steatosis (*Chen Y, Vasiliou V et al, manuscript in preparation*). Thus, $Gclm^{-/-}$ mice represent a model wherein significant GSH depletion in the liver is associated with beneficial metabolic and stress responses to ethanol.

22.8 Concluding Remarks

Alcohol use is widespread and related to numerous diseases, including oral, colorectal, liver, pancreas, aerodigestive, breast, and colon cancers. Ethanol metabolism and resultant oxidative stress are primary pathogenic events mediating alcohol-induced organ damage and neurobehavioral changes, the molecular details of which are not yet fully understood. The knockout mouse models for enzymes metabolizing ethanol (ADH1, CAT, and CYP2E1), acetaldehyde (ALDH2, ALDH1A1, and ALDH1B1) and enzymes involved in GSH synthesis (GCLC and GCLM), which we have discussed briefly in this review, represent unique and highly relevant animal models for alcohol research. Utilization of these models will deliver valuable information about the fundamental mechanisms underlying ethanol toxicity. Such knowledge should accelerate the development of more effective, targeted therapies to both prevent and treat health issues associated with excessive alcohol consumption.

Abstract: The aim of this study was to determine the beneficial effect of glycyrrhizic acid (GA) on type 2 diabetic nephropathy using renal tubular epithelial cell line (NRK-52E). The cells are divided into normal group (NG), high glucose group (HG), and treatment group (HG + GA). The methylthiazoletetrazolium (MTT) assay was used to detect the cell proliferation. Cell cycle analysis was performed using flow cytometry. Model driven architecture (MDA), reactive oxygen species (ROS) and superoxide dismutase (SOD) were also measured. Electron microscopy and histological were used to detect the changes in cell ultrastructure. The phosphorylation of AMP-activated protein kinase (AMPK), silent information regulator T1 (SIRT1), manganese-superoxide dismutase (Mn-SOD) and transforming growth factor-β1 (TGF-β1) were assessed by immunohistochemistry, immunofluorescence, and western blotting. Real-time fluorescent quantitative PCR (RT-qPCR) was used to measure Mn-SOD and PPARγ co-activator 1α (PGC-1a) mRNA. We find that high glucose increases NRK-52E cell proliferation and TGF-β1 expression, but decreases expression of AMPK, SIRT1 and Mn-SOD. These effects are significantly attenuated by GA. Our findings suggest that GA has protective effects against high

glucose-induced cell proliferation and oxidative stress at least in part by increasing AMPK, SIRT1 and Mn-SOD expression in NRK-52E cells.

Keywords: diabetic nephropathy; glycyrrhizic acid; NRK-52E

1. Introduction

Diabetic nephropathy (DN), one of the most severe microvascular complications of type 1 and type 2 diabetes, is a major cause of end-stage renal disease [1]. It seriously affects patients' life quality. Pathological manifestations of DN include glomerular hypertrophy, basement membrane thickening and accumulation of extracellular matrix, tubulo-interstitial disease, and glomerulosclerosis. The pathogenesis of DN is very complex and has not been fully elucidated. High glucose is the foundation and key of DN, and can induce an abnormal increase of reactive oxygen species (ROS) and oxidative stress occurrence. In addition, high glucose can induce abnormal glucose metabolism and hemodynamic changes. High glucose-induced renal tubular epithelial cells have been used as an *in vitro* model for studies of early-stage DN.

Tubular epithelial cells account for 90% of the total kidney volume. Recent studies showed that the degree of seriousness of tubular interstitial disease is closely related to the DN renal dysfunction. The early-stage DN mainly results in glomerular proteinuria, but its long-term prognosis depends on the severity of tubulointerstitial damage. Tubular epithelial cell hypertrophy is a major factor in causing kidney hypertrophy. Therefore, the early hypertrophy inhibition for diabetic renal tubular epithelial cells helps to control the DN disease.

Functions of tubular epithelial cells can be affected by many external factors such as transforming growth factor-β (TGF-β). In the normal situation, TGF-β can inhibit the cell proliferation and inflammation. However, over-expression of TGF-β may cause pathological changes and promote cell proliferation and extracellular matrix accumulation. The increase of ROS and model driven architecture (MDA) generation, and decrease of antioxidant enzyme superoxide dismutase (SOD) activity are the result of oxidative stress. Studies have shown that high glucose-induced oxidative stress and renal cortical injury is related to down-regulation of PPARγ co-activator 1α (PGC-1α) expression [2].

AMP-activated protein kinase (AMPK) is a serine/threonine kinase evolutionarily conserved with a catalytic α-subunit and regulatory β- and γ-subunits, forming a heterotrimeric complex. It is abundantly expressed in the kidney [3]. AMPK has become a hot research subject for type 2 diabetes. Previous studies have shown that manganese superoxide dismutase (Mn-SOD) can reduce high glucose induced increase of ROS, thereby activate AMPK [4].

Glycyrrhizic acid (GA) is a triterpenesaponin glycoside, which is the primary bioactive component of jor plant root extract of *Glyccyrhiza Glabra* (Liquorice), a shrub from the Leguminosae family [5,6]. Recently, a study showed that GA was able to protect rabbits from renal ischemia reperfusion injuries [7]. Another report shows that after treating diabetic rats with glycyrrhizin for 60 days, TGF-β1 expression in renal tissue was decreased [8].

However, little information is available about the effect of GA on the proliferation of tubular epithelial cells induced by high glucose. The aim of this study was to test the hypothesis if GA has a protective effect

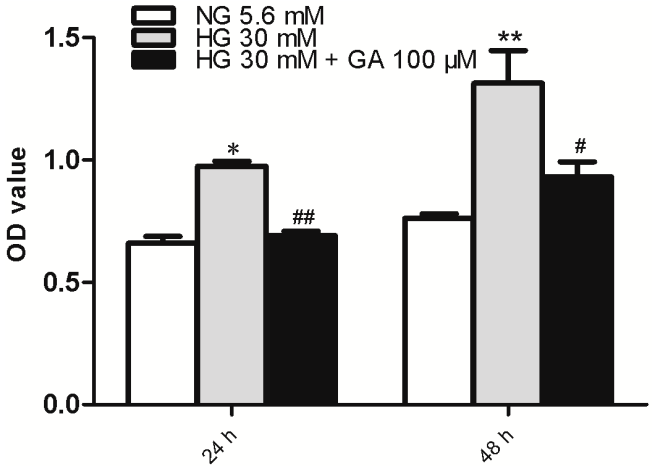
against high glucose-induced tubular epithelial cells damage by reducing cell proliferation and oxidative stress. We employed multiple approaches to examine the expression of factors such as AMPK, SIRT1 (silent information regulator T1), Mn-SOD and TGF-β1 in NRK-52E cells in the absence or presence of high glucose, GA, or both. Our data are consistent with our hypothesis.

2. Results and Discussion

2.1. GA (Glycyrrhizic Acid) Reverses the High Glucose-Induced Effect on Cell Proliferation in NRK-52E Cells

NRK-52E cell proliferation was evaluated using MTT (methylthiazoletetrazolium) analysis. The results showed that compared with the NG (normal group) group, 30 mM glucose alone increased NRK-52E cell proliferation at both 24 and 48 h time points ($p < 0.05$). We tested the effect of GA at 25, 50, 100, 200 μmol/L and found GA at 100 μmol/L can inhibit NRK-52E cell proliferation induced by HG ($p < 0.05$) (Figure 1).

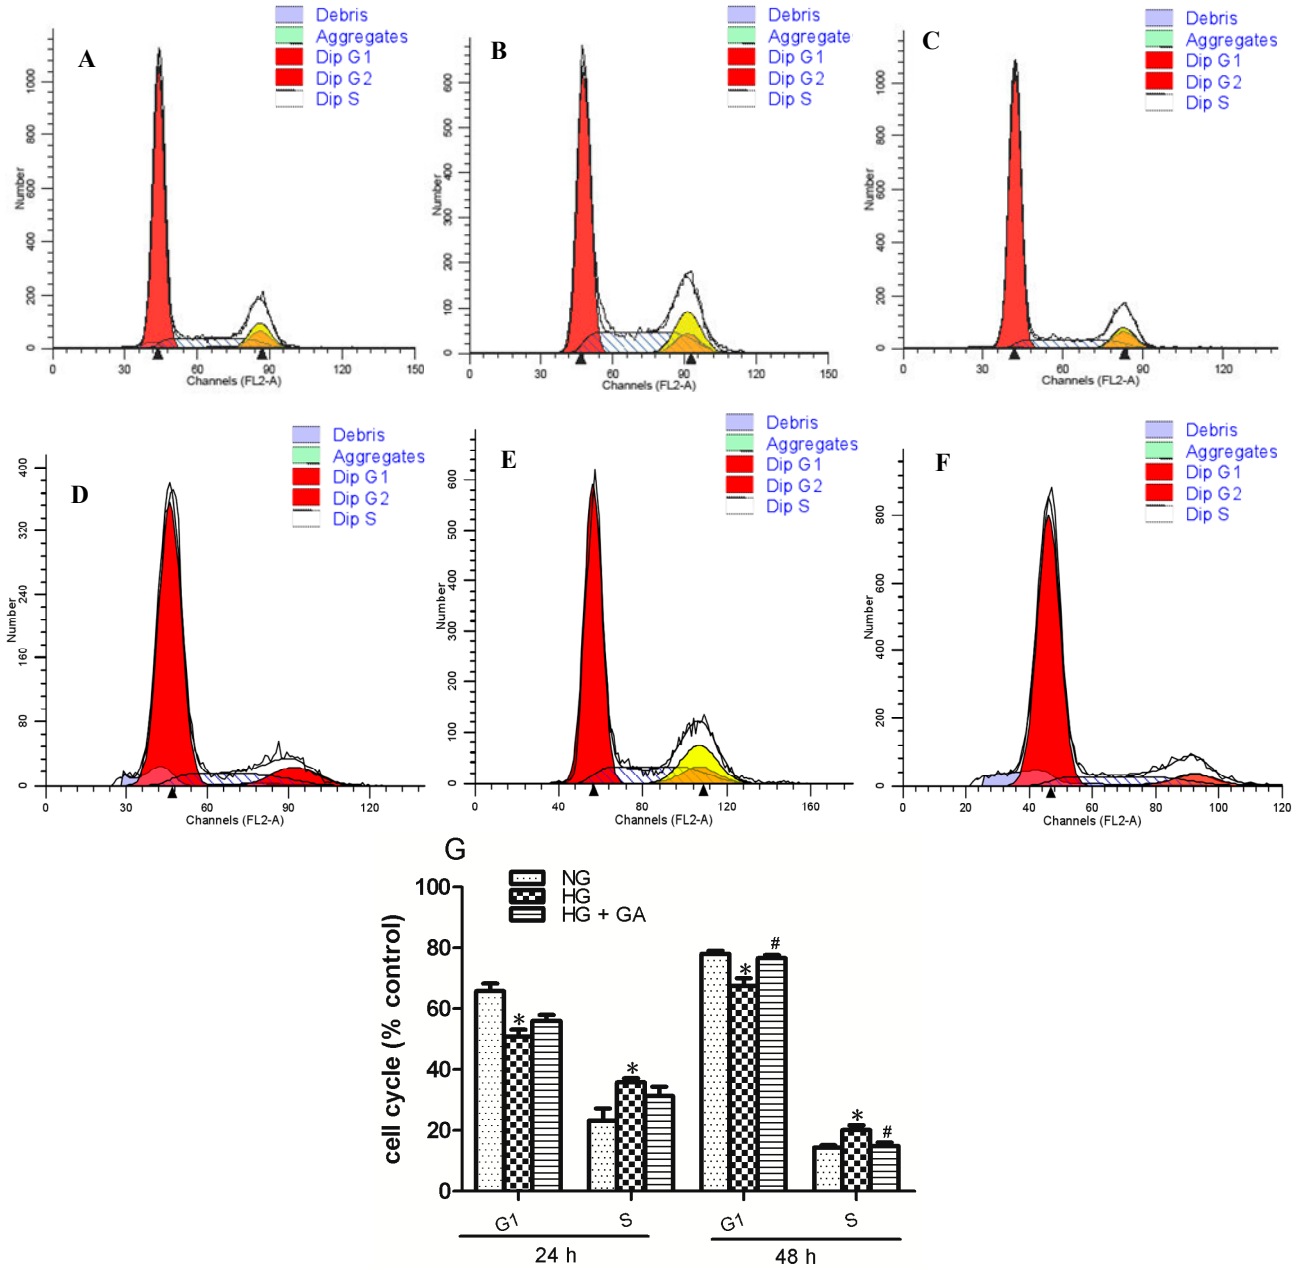
Figure 1. Proliferation assay. NRK-52E cells were treated with high glucose (HG) with or without glycyrrhizic acid (GA) as indicated for 24 or 48 h, followed by MTT (methylthiazoletetrazolium) analyses. Cells receiving normal glucose (NG) were included as control. $n = 3$. * $p < 0.05$ *vs.* NG; ** $p < 0.01$ *vs.* NG; $^{\#}$ $p < 0.05$ *vs.* HG; $^{\#\#}$ $p < 0.01$ *vs.* HG. OD (optical density).



2.2. Effect of GA on Cell Cycle Induced by HG (High Glucose) in NRK-52E Cells

A flow cytometry was used to evaluate the effect of GA treatment upon cell cycle profiles (Figure 2A–F). After 24 and 48 h incubation in HG group, the proportion of G1 phase decrease and S phase increase in NRK-52E cells ($p < 0.05$). In contrast, more cells in G1 phase and fewer cells in S phases were significantly obtained in GA group after 48 h incubation. ($p < 0.05$). At 24 h time point, GA did not significantly increase the number of cells in G1 ($p > 0.05$), or decrease the cells number in S phase ($p > 0.05$), compared with HG group (Figure 2G).

Figure 2. Flow cytometric analysis of the cell cycle. Cells were treated for 24 or 48 h as indicated, (**A**) NG group; (**B**) HG group; (**C**) HG + GA group (treated with 24 h); (**D**) NG group; (**E**) HG group; (**F**) HG + GA group (treated with 48 h); and (**G**) Followed by flow cytometric analysis. * $p < 0.05$ *vs.* NG; $^{\#}$ $p < 0.05$ *vs.* HG.



2.3. Histopathological Findings

For the NG group, most of NRK-52E cells were round or oval-shaped. Cilia existed in membrane. Organelles were normal. Membrane integrity was good. For the HG group, some cells increased volumes significantly. The number of round cells also increased. Cells tended to change fusiform (Figure 3). The cells incubated in HG exhibited injury features, including an irregular nucleus, chromatin condensation, nuclear envelope shrinkage, organelle shortage, rough endoplasmic reticulum slight expansion, cilias fusion and shortage. The situation became much better in the groups treated with GA (final concentration of 100 μmol/L) in comparison with the HG group (Figure 4).

Figure 3. Effect of GA on cell morphology induced by HG in NRK-52E cells. The cells were incubated in the three groups for 24 h. They were stained with hematoxylin-eosin. Original magnification: ×200.

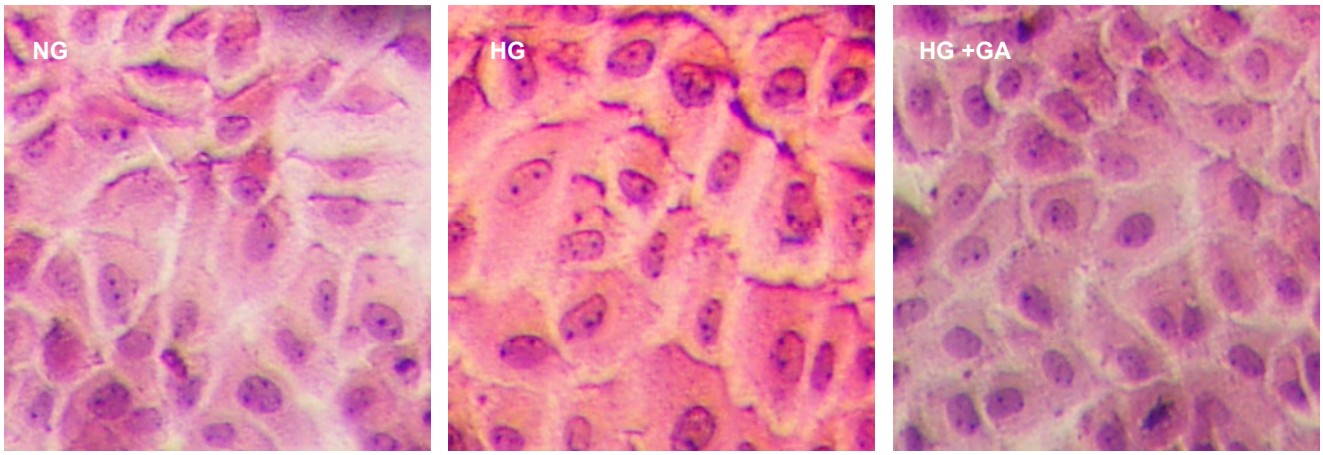


Figure 4. Electron microscopy analyses. NRK-52E cells were grouped and treated as in Figure 1 and examined under an electron microscopy after 48 h. (**A**,**D**) NG group; (**B**,**E**) HG group; (**C**,**F**) HG + GA group. **A**–**C**: ×4000, **D**–**E**: ×1000.

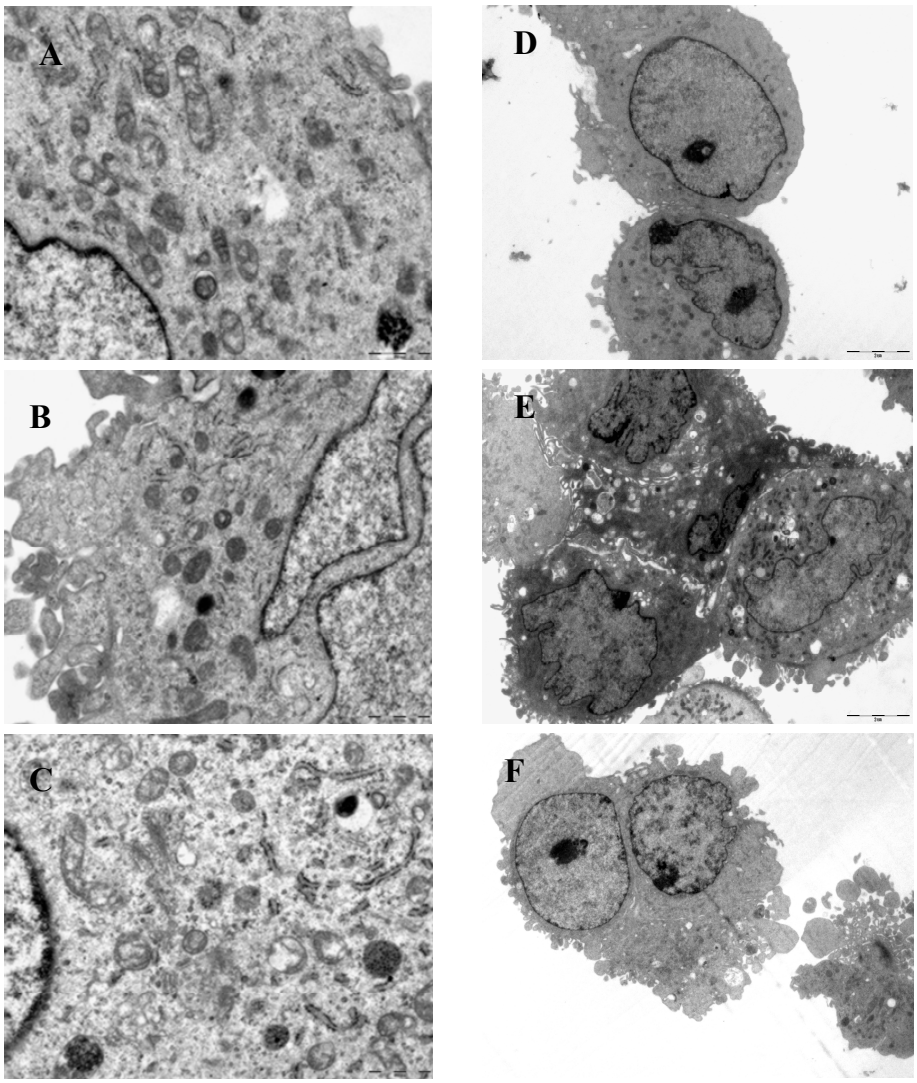

2.4. Effect of GA on SIRT1 (Silent Information Regulator T1), AMPKα (AMP-Activated Protein Kinase α), Mn-SOD (Manganese-Superoxide Dismutase) and TGF-β1 (Transforming Growth Factor-β1) Proteins Expression

SIRT1, AMPKα and Mn-SOD proteins were detected by immunohistochemistry (Figure 5A and Table 1) and immunofluorescence (Figure 5B,C). TGF-β1 was detected by immunohistochemistry. The results showed that the fluorescence intensity and optical density in the HG group were lower than that in the control group for SIRT1, AMPKα and Mn-SOD ($p < 0.05$). SIRT1 and Mn-SOD increased in the GA group ($p < 0.05$). However, for AMPKα, it increased only at 48 h but not at 24 h ($p > 0.05$). Immunohistochemical experiment showed that HG increased TGF-β1 protein expression, which was reversed in the GA group ($p < 0.05$).

Figure 5. Immunohistochemistry and immunofluorescence analyses. (**A**) NRK-52E cells were grouped and treated as in Figure 1 for 24 h, followed by immunohistochemistry to assess expression of proteins as indicated. Original magnification: ×400; (**B**) As in **B**, except that cells were analyzed by immunofluorescence staining. Original magnification: ×200; and (**C**) Relative levels of protein expression. * $p < 0.05$ *vs.* NG; # $p < 0.05$ *vs.* HG. Apoptosis is labeled with arrow.

Experimental group (48 h)	0.25 ± 0.006 #	0.18 ± 0.005 #	0.28 ± 0.024 #	0.26 ± 0.037 #

* $p < 0.05$ *vs.* NG; ** $p < 0.01$ *vs.* NG; # $p < 0.05$ *vs.* HG; ## $p < 0.01$ *vs.* HG.

2.5. Effect of GA on SIRT1, AMPKα, Mn-SOD and TGF-β1 Proteins Expression, as Detected with Western Blotting

In our experiment, there was a decrease in the expression of AMPKα, SIRT1 and Mn-SOD, and an increase in the expression of the TGF-β1 after treatment of cells with HG. However, the treatment with GA antagonized all the above effects induced by HG (Figure 6A,B).

Figure 6. Western blotting analyses. NRK-52E cells were grouped and treated as in Figure 1 for 24 and 48 h, followed by Western blotting to evaluate expression of proteins as indicated, with Actin as an equal loading control. (**A**) Western blot detect purpose proteins treated with 24 and 48 h pictures; (**B**) Relative levels of protein expression. The intensity of the bands on Western blots were quantified, normalized to Actin, and graphed. * $p < 0.05$ *vs.* NG; # $p < 0.05$ *vs.* HG.

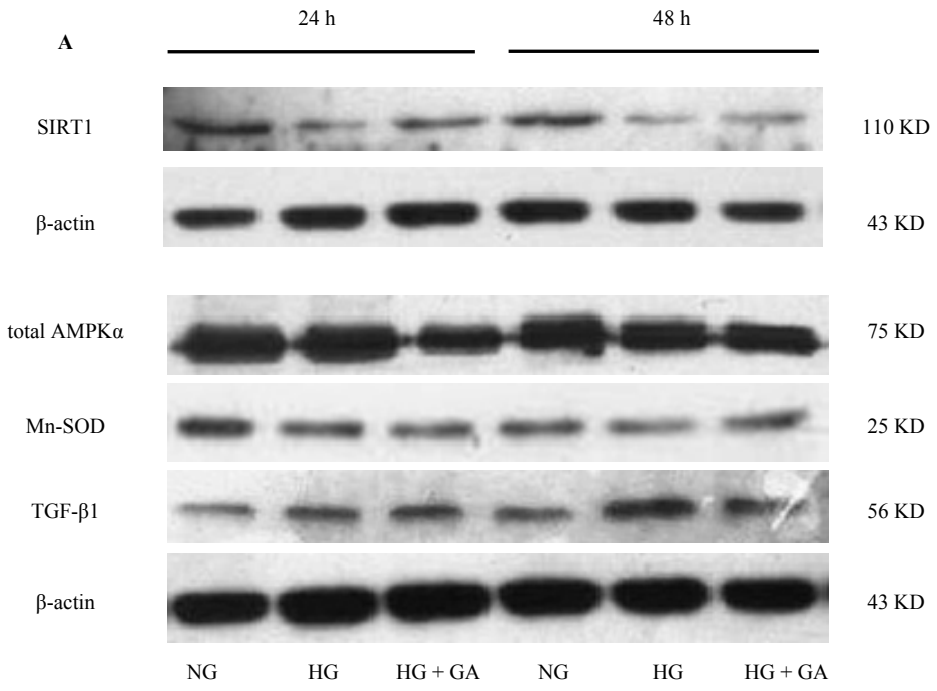

Figure 6. *Cont.*

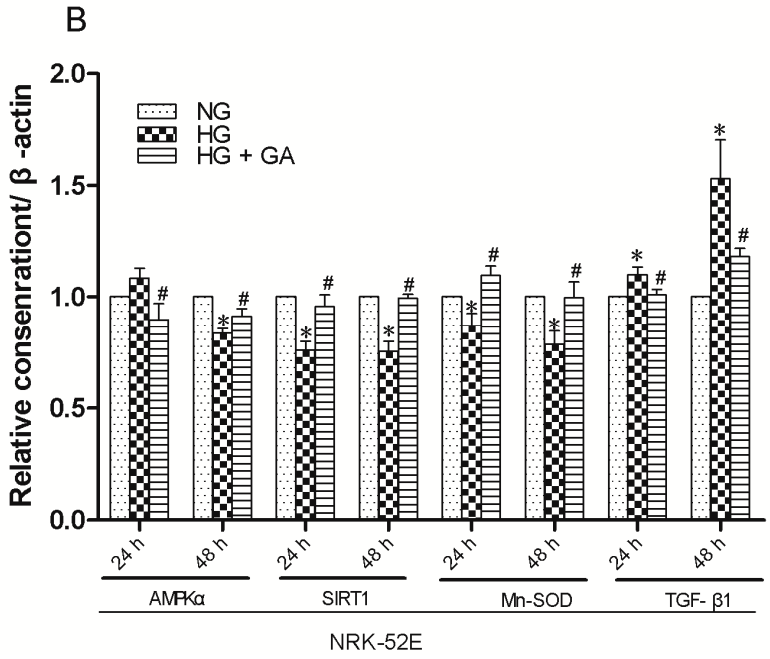


2.6. Effects of GA on Activities of Antioxidant Enzymes and Oxidative Stress Markers

The activity of SOD and concentration of MDA were lower, whereas concentration of MDA was higher in the HG group than in the control group ($p < 0.05$), suggesting that the cells were suffered from oxidative stress (Table 2). Treatment with GA significantly decreased the concentrations of MDA and significantly increased SOD activity ($p < 0.05$). These results indicate that GA ameliorates oxidative stress in high glucose cells.

Table 2. Effect of GA on model driven architecture (MDA) and SOD in NRK-52E cells.

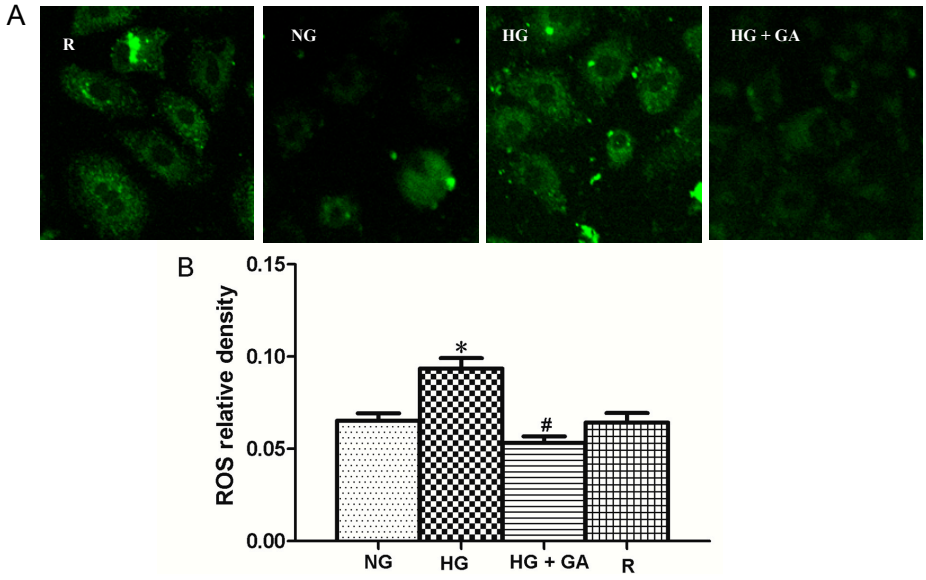
Group (n = 3)	MDA (μmol/L)	SOD (U/mL)
Normal group	7.57 ± 0.680	23.60 ± 0.538
High glucose group	14.66 ± 0.480 **	16.22 ± 0.315 **
Experimental group	9.77 ± 0.468 $^{\#\#}$	19.68 ± 0.952 $^{\#}$

** $p < 0.01$ *vs.* NG; $^{\#}$ $p < 0.05$ *vs.* HG; $^{\#\#}$ $p < 0.01$ *vs.* HG.

2.7. Effect of High Glucose and GA on ROS (Reactive Oxygen Species) Production

We observed that the ROS production was augmented in NRK-52E cells induced with high glucose, peaking after 24 h of treatment (Figure 7A). With the addition of GA, it was decreased. These data indicate that after giving GA, there appears either a decrease in ROS generation or an increase in endogenous ROS scavenging/antioxidant capacity.

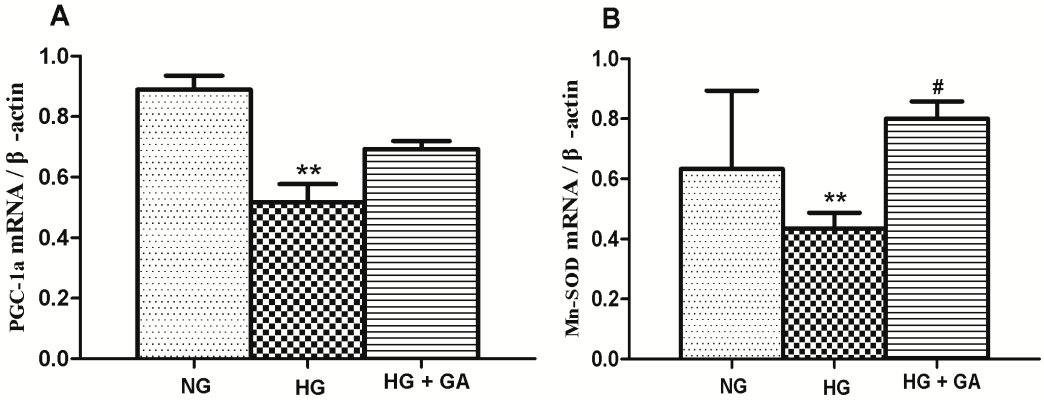
Figure 7. High glucose induces ROS (reactive oxygen species). Cells were grouped and treated for 24 h as indicated, followed by DCFH-DA (2',7'-dichlorofluorescin diacetate) (probe) or rosup (positive control) treatment for 30 min. Cell were then analyzed, using confocal microscopy. R represents rosup. (**A**) confocal microscopy images; (**B**) Histograms. * $p < 0.05$ *vs.* NG; # $p < 0.05$ *vs.* HG.



2.8. Effect of GA on the Expression of Mn-SOD and PGC-lα (PPARγ Co-Activator 1α) mRNA

The effects of GA on Mn-SOD and PGC-lα mRNA in NRK-52E cells have been examined. Exposure of NRK-52E decreased the expression of Mn-SOD and PGC-lα mRNA level in the HG group compared with NG group. The expression of Mn-SOD increased in GA group ($p < 0.05$), but PGC-lα mRNA level did not increase in GA group (Figure 8A,B) ($p > 0.05$).

Figure 8. Real-time RT-qPCR analyses. Effect of GA on Mn-SOD (**A**) and PGC-1α (PPARγ co-activator 1α) (**B**) mRNA expression was measured by real-time fluorescent quantitative RT-qPCR. Values were normalized to mouse housekeeping gene β-actin and then normalized to sham samples. The mRNA levels of Mn-SOD and PGC-1α in the HG group were significantly lower than those in the NG group (** $p < 0.01$). The mRNA levels of Mn-SOD began to return to higher levels in the GA group (# $p < 0.01$). But no change was observed in PGC-lα mRNA level for GA group compared with HG group.



2.9. Discussion

Previous studies have shown that high glucose concentrations promote proliferation of mesangial cells, renal tubular epithelial cells, and vascular smooth muscle cells under the diabetic state [9]. In this study, 30 mmol/L high glucose was used as the stimulator to induce NRK-52E cell proliferation. Rat renal tubular epithelial cells induced by high glucose as an *in vitro* model have been used in studies of early-stage diabetic nephropathy. Clinical trials have shown that high glucose is the principal cause of renal damage in both type 1and type 2 diabetes [10]. MTT is a method to detect cell proliferation activity and was used in this study to detect the NRK-52E cell proliferation. The results shows that high glucose significantly increases NRK-52E cell proliferation after intervention for 24 and 48 h. This demonstrated that NRK-52E cells can be used as *in vitro* model of diabetic nephropathy after injury through induction with 30 mmol/L high glucose. It was also shown that GA can inhibit the cell proliferation induced by HG at the concentration of 100 μmol/L.

Reponses of mesangial cells to injuring stimuli include proliferation, hypertrophy and apoptosis. The degree of these injuries depends on the progress of the cell cycle. In cell cycle progression, traversing the G1-S phase boundary is coupled to DNA synthesis. In vitro, high glucose can promote mesangial cells from G1 to S phase, reducing the proportion of cells in G1 phase, and increasing the proportion of cells in S phase. The high glucose also causes DNA synthesis and promotes cell proliferation [11]. It was shown that GA can inhibit DNA synthesis, resulting in arrest of the cell-cycle transition from G1 to S phase. Compared with NG group, high glucose significantly increased the NRK-52E cells population at S-phase, whereas 100 μmol/L GA blocked the G1-S phase transition after the cells were treated for 48 h. GA may be involved in inhibiting cell proliferation.

These results suggest that GA inhibits high glucose-induced mesangial cell proliferation to execute its protective effect on NRK-52E cell injury.

Although the mechanisms of proliferation of NRK-52E cells induced by high glucose are still poorly defined, mechanism of ROS is well documented in both diabetes and model systems. In addition, high glucose has been frequently shown to augment cell proliferation and DNA synthesis, and it has been suggested as the main contributor to DN in affected subjects [12]. The importance of elevated ROS level in the pathogenesis of the diabetes-related microvascular complications has been well documented [12,13]. High glucose-induced increase of ROS is an important aspect of oxidative stress. The results shows that ROS increased in HG group compared with the NG group. However, it was decreased in GA group compared with the HG group.

The cellular levels of ROS and the presence of oxidative stress are determined not only by rates of ROS generation, but also by their neutralization and degradation using endogenous antioxidants. Oxidative stress leads to lipid peroxidation and thereby formation of the harmful product such as MDA [14]. Accordingly, it induces DNA oxidative damage via generation of 8-OHdG (8-hydroxy-2-deoxy Guanosine) [15]. Meanwhile, the activity of antioxidant defense enzymes decreases [16], which leads to cell damage. The reduced activity changes the oxidative stress markers: decreasing SOD levels and increasing MDA. It was reported that an anti-oxidative role of GA in the amelioration of carbon tetrachloride-induced liver injury [17].

The peroxisome PGC-1α is a small family of transcriptional coactivators, which play a critical role in the control of glucose, lipid, and energy metabolism [18]. The physiological significance of PGC-1α in

mitochondrial energy metabolism has been well demonstrated [19,20]. Studies have shown that high glucose-induced renal cortical injury and oxidative stress is related to down-regulation of PGC-1α. When PGC-1α stimulates mitochondrial biogenesis, SOD generation increases [21]. Therefore, when PGC-1α down-regulates, oxidation and antioxidant system become imbalanced and oxidative stress occurs. In this experiment, we used RT-qPCR method to detect the PGC-1α mRNA. The result showed that compared with NG group, PGC-lα mRNA decreased in HG group. There was no different in GA group compared with HG group.

These results showed that high glucose can promote ROS generation, decrease SOD and increase MDA in NRK-52E cells. It was further confirmed that high glucose can induce ROS production, promote lipid peroxidation, and decrease antioxidant capacity. In GA group, however, it was observed that GA had an antioxidant role, ROS, causing MDA to decrease and SOD to increase. We also used RT-qPCR method to detect the Mn-SOD mRNA. The result showed that Mn-SOD mRNA increase in GA group. These results suggest that GA can reduce the oxidative stress, improve antioxidant system to protect cells from damage. However, the protective effect of glycyrrhizin on high glucose-induced NRK-52E cells' oxidative stress injury may not be regulated by PGC-1α after treatment for 24 h.

Since AMPK is a cellular energy sensor, its activity is highly linked to the change in the intracellular AMP/ATP ratio. The role of AMPK in carbohydrate and protein metabolism, cell cycle regulation, and in mitochondrial biogenesis has been described in literature. AMPK also regulates glucose homeostasis. Insulin deficiency has been proposed as one of the factors causing hypothalamic. AMPK activation and the subsequent increase in food intake have been observed in streptozotocin-induced diabetic rats [22]. Renal AMPK activity was reduced after a high-fat diet (HFD) for 16 weeks [23]. However, its role in mediating renal inflammation was rarely evaluated. Adiponectin and rosiglitazone can activates AMPK through improving insulin sensitivity. We used immunohistochemistry, immunofluorescence and western blot experiments to detect AMPK protein expression. The results showed that AMPKα has a wealth expression in the NRK-52E cells. AMPKα protein expression decreased in high glucose group. GA could make AMPKα protein expression increased after treatment for 48 h. It also showed that AMPK was localized in the cytoplasm.

Sirt1, a NAD-dependent protein deacetylase, is reported to regulate intracellular metabolism and attenuate ROS-induced apoptosis, leading to longevity and acute stress resistance. Both AMPK and SIRT1 have emerged as interesting targets as they are heavily involved in catabolic metabolism, mitochondrial activation, angiogenesis and enhanced cell survival [24–27]. It is well known that the effects of resveratrol are mediated by both SIRT1 and AMPK [28]. However, the direct relationship between kidney-specific Sirt1 and renal tissue survival *in vivo* has not been elucidated. In this study, immunohistochemistry, immunofluorescence and western blot experiment showed that high glucose can reduce the expression of SIRT1, which may be attentuated after giving GA.

TGF-β1 is a key intermediary substance in DN. TGF-β1 can form an autocrine activation of proliferation ring in an autocrine manner to prevent glomerular mesangial cells, epithelial, endothelial cells and proximal tubule cell from proliferation, differentiation and increasing cell diameter. In early diabetic, glomerular and tubular hypertrophy plays an important role. The experimental showed that TGF-β1 protein expression was significantly increased in HG group after 24 and 48 h, which may be reduced after giving GA. Morphology shows that cells were flat in HG group compared with NG group. In the electron microscope after 48 h treatment, stimulation showed that NRK-52E cell's volume

increased comparing to NG group. This suggests that cells hypertrophy in HG group relates to high expression of TGF-β1.

These results suggest that GA protects NRK-52E cells from damage through regulating the expression of AMPK, SIRT1, Mn-SOD and TGF-β1. NRK-52E cells hypertrophy induced by high glucose correlates to high expression of TGF-β1.

3. Experimental Section

3.1. Materials

Cell culture reagents, trypsin EDTA (Calcium disodium), fetal bovine serum (FBS) were obtained from Hyclone laboratories Inc. (South Logan, UT, USA). Flasks, vials, 24 Well cell culture cluster, 96 well cell culture cluster and straws were purchased from Corning Incorporated (Corning, NY, USA). Glycyrrhizin was come from Tokyo Chemical Industry Co. (TCI, Tokyo, Japan). D-(+)-glucose powder was purchased from Sigma (St. Louis, MI, USA). NRK-52E cells were obtained from Chinese Center for Type Culture Collection (Shanghai, China). MTT (5 mg/mL) and cell cycle detection kits were purchased from Keygen Biotech (Nanjing, China). Reaction Oxygen Species Assay Kit was purchased from Beyotime (Shanghai, China). SOD and MDA kits were obrained from Nanjing Jiancheng (Nanjing, China). The antibodies recognizing AMPKα, SIRT1 and Mn-SOD were purchased from Santa Cruz (TX, USA). Anti-β-actin was purchased from Bios (Beijing, China). Trizol was purchased from Invitrogen (Grand Island, NY, USA). Other commercial kits of the Transcript RT/RI Enzyme Mix and the TransStart Top Green qPCR SuperMix were obtained from TransGen Biotech (Beijing, China). All other reagents were from commercial sources and of standard biochemical quality.

3.2. Cell Culture

The cells were cultured in DMEM (Dulbecco's modi-fied Eagle's medium) supplemented with 10% fetal calf serum, 100 U/mL penicillin, and 100 μg/mL streptomycin at 37 °C in an atmosphere containing 5% CO_2. After preincubation in DMEM supplemented with 0.5% fetal calf serum for 24 h, cells were then treated in three different groups: normal glucose group (NG, 5.6 mM glucose), high glucose group (HG, 30 mM glucose), and high glucose and glycyrrhizic acid group. Cells were incubated for another 24 or 48 h before analyses.

3.3. Cell Proliferation Assay

MTT assay was used to measure cell proliferation. After 24 and 48 h incubation with different compounds as described above, 50 μL MTT was added and cells were cultured for additional 4 h. Subsequently, cells were lysed using dimethylsulfoxide. When the formanzan crystals were completely dissolved, the density (OD) was measured at 490 nm, using a Spectrophot-ometer Microplate Reader come from BioTek (Winooski, VT, USA).

3.4. Flow Cytometry

After 24 or 48 h treatment with different compounds, cells were harvested by trypsinization without EDTA. They were then centrifuged (with 1000× *g*, 10 min, 4 °C) and washed twice with phosphate buffered saline (PBS). Then they were fixed in methanol at 4 °C overnight. Following two washes with PBS, the fixed cells were incubated in RNase at 37 °C for 30 min, followed by a DNA staining with propidium iodide at 4 °C for 30 min in the dark. Then each sample was analyzed using a Flow Cytometer (BD FACSCalibur, Biocompare, San Diego, CA, USA) and the proportion of cells within the G1 and S phases of the cell cycle were determined.

3.5. Histological Studies

After cells were intervened 24 h, the cells were fixed in 95% ethanol. Then stained with hematoxylin-eosin. The stained sections were examined and photographed with a light microscope (BX61, Olympus, Tokyo, Japan).

3.6. Electron Microscopy

After cells were intervened 48 h, they were fixed with 4 °C, then washing with 0.1 mol cacodylate buffer. Experimental procedure includes before fixation, after fixation, dehydration, embedding, slicing and uranyl acetate dye staining. TEM (transmission electron microscopic) comes from H7650 (Hitachi, Shiga, Japan).

3.7. Immunohistochemistry Assay

Cells were incubated with antibodies specific for AMPKα, SIRT1, Mn-SOD (1:200) and TGF-β1 (1:100, BOSTER, Wuhan China) overnight, followed by secondary antibody incubation in IHC Detection Reagent (ZSGB-BIO, Beijing, China) in 37 °C for 45 min. DAB (ZSGB-BIO) was used to stain cytoplasm. Then hematoxylin was used to stain nucleus. Cells were then examined and photographed with light microscope (BX61). Ipwin32 software was used to quantify optical density.

3.8. Immunofluorescence Assay

The cells were cultured on glass coverslips and were treated for 24 and 48 h after growth arrest. Cells were fixed in 4.0% formaldehyde, then blocked with goat serum. Immunofluorescence staining was performed by incubating the fixed cells with anti-AMPKα, SIRT1 and Mn-SOD antibodies (1:200), followed by incubation with FITC (fluorescein isothiocyanate)-conjugated secondary antibody (1:40, Protein Tech Group, Chicago, IL, USA). Cells were viewed with an Olympus FV1000 Laser Scanning Confocal Microscope (Olympus, Center Valley, PA, America). Ipwin32 software (Media Cybernetics Inc., Bethesda, MD, USA) was used to quantify fluorescence intensity.

3.9. Western Blotting

After being treated with different compounds for 24, 48 h, cells were harvested and washed with ice-cold phosphate buffer. Protein was obtained using whole-cell extraction kit (Keygen biotech,

Beijing, China). Protein concentrations were determined using the BCA method (Keygen biotech). Equal amounts of protein were loaded, separated by SDS-PAGE (SDS-polyacrylamide gel) and transferred to nitrocellulose membranes. After being blocked with 5% skimmed milk in Tris-phosphate buffered saline (TPBS) at room temperature, the membranes were incubated overnight at 4 °C with primary antibodies for AMPKα, SIRT1, Mn-SOD (1:300), TGF-β1 (1:100), and Rabbit An-β-Actin (1:1000). After being incubated with the respective second antibody, immune complexes were detected using ECL (chemiluminescent agent) (Amersham Life Science, Arlington Heights, IL, USA) Western blotting reagents. Immunoreactive bands were quantified using the Bio-RAD Gel Imaging System (Bio-RAD, Berkeley, CA, USA). Values were corrected with the internal control (β-actin).

3.10. UV Spectrophotometer

After cells were cultured for 24 h, UV spectrophotomete (VIS-7220N, Beijing, China) was used to detect OD of SOD and MDA between different groups.

3.11. ROS Detection

The cells were cultured on glass coverslips and incubated in the dark with 10 μM/L of DCF (dichlorofluorescein) or Rosup for 30 min at 37 °C. Intracellular ROS production was assessed with an Olympus FluoView 1000 Laser Scanning Confocal Microscope (OLYMPUS) (using ex/em λ = 488 nm/515 nm for DCFH-DN).

3.12. Quantitative Real Time Polymerase Chain Reaction PCR Assay

RNA was extracted using the Trizol reagent, reversely transcribed with an RT kit using oligo (dT) 18 primer (0.5 μg/μL) in a total volume of 20 μL according to Manufacturer's protocol. Real-time PCR was performed and analyzed on a Fluorescent PCR instrument (IQ-5) using cDNA and SYBR Green PCR Master Mix. The primers used were: Mn-SOD forward: 5'-AAGGAGCAAGGTCGCTTACAGA-3', Mn-SOD reverse: 5'-CAAATGGCTTTCAGATAGTCAGGTC-3', PGC-1α forward: 5'-AATCAAGC CACTACAGACACCGC-3', PGC-1α reverse: 5'-CTTTCGTGCTCATTGGCTTCAT-3', The relative amounts of mRNA were determined by the $2^{-\Delta\Delta Ct}$ calculations.

3.13. Statistical Analysis

All quantitative data are expressed as mean ± SD. The differences between two experimental conditions were analyzed using the Student's *t* tests and/or one-way analysis of variance (ANOVA). $p < 0.05$ was considered statistically significant.

4. Conclusions

We concluded that the GA treatment resulted in protective effects on NEK-52E cell injuries induced by high glucose. The protection is obtained by inhibiting the high-glucose induced up-regulation of oxidation factor ROS and MDA, and down-regulation of SOD. However, the protective effect of glycyrrhizin on high glucose-induced NRK-52E cells' oxidative stress injury may not be regulated by PGC-1α. In addition, GA may increase AMPK, SIRT1 and Mn-SOD proteins expression and decreased

expression of TGF-β1 induced by HG. NRK-52E cells hypertrophy induced by high glucose may relate to high expression of TGF-β1. At the cell level, GA may be a potential therapeutic agent for the early stage of DN.

ABSTRACT

Background: Glycyrrhizin, silymarin, and ursodeoxycholic acid are widely used hepatoprotectants for the treatment of liver disorders, such as hepatitis C virus infection, primary biliary cirrhosis, and hepatocellular carcinoma.
Purpose: The gene expression profiles of HepG2 cells responsive to glycyrrhizin, silymarin, and ursodeoxycholic acid were analyzed in this study.
Methods: HepG2 cells were treated with 25 μM hepatoprotectants for 24 h. Gene expression profiles of hepatoprotectants-treated cells were analyzed by oligonucleotide microarray in triplicates. Nuclear factor-κB (NF-κB) activities were assessed by luciferase assay.
Results: Among a total of 30,968 genes, 252 genes were commonly regulated by glycyrrhizin, silymarin, and ursodeoxycholic acid. These compounds affected the expression of genes relevant various biological pathways, such as neurotransmission, and glucose and lipid metabolism. Genes involved in hepatocarcinogenesis, apoptosis, and anti-oxidative pathways were differentially regulated by all compounds. Moreover, interaction networks showed that NF-κB might play a central role in the regulation of gene expression. Further analysis revealed that these hepatoprotectants inhibited NF-κB activities in a dose-dependent manner.
Conclusion: Our data suggested that glycyrrhizin, silymarin, and ursodeoxycholic acid regulated the expression of genes relevant to apoptosis and oxidative stress in HepG2 cells. Moreover, the regulation by these hepatoprotectants might be relevant to the suppression of NF-κB activities.

Introduction

Liver cancer is the second most common cause of cancer death worldwide, causing about 746,000 deaths in 2012. The prognosis of liver cancer is very poor and the estimated incidence of new cases is 782,000 in the less developed regions in 2012 (Ferlay et al. 2015). Several studies illustrate that constitutive nuclear factor-κB (NF-κB) activity plays a central role in the hepatic neoplastic progression through the upregulation of anti-apoptotic genes (Kucharczak et al., 2003). Moreover, the inhibition of NF-κB activation in hepatocytes retards and reduces the development of hepatocellular carcinoma in mice (DiDonato et al. 2012). Therefore, the inhibition of NF-κB activation might be an effective strategy to treat liver cancers.

Glycyrrhizin, the triterpenoid saponin from *Glycyrrhiza glabra* L. roots (licorice), consists of one molecule of glycyrrhetinic acid and two molecules of glucuronic acid. Glycyrrhizin exhibits various pharmacological effects, such as anti-inflammatory and protective effects in liver (Li et al. 2014). Therefore, glycyrrhizin analogs, such

0944-7113/

as magnesium isoglycyrrhizinate and stronger neo-minophagen C, are effective and safe for the treatment of patients with chronic liver disease and liver dysfunction (Mori et al. 1990; Mao et al. 2009).

Silymarin is a flavonolignan complex from *Silybum marianum* (L.) Gaertn. fruits. Silymarin comprises a number of flavonolignans, including silibinin (silybin A and silybin B), isosilybin A and B, silychristin A and B, silydianin, and other phenolic compounds (Wu et al. 2009). Silymarin exhibits anti-inflammatory and immunomodulatory effects and thus promotes the health of livers (Polyak et al. 2013). In addition, silymarin-type drugs like legalon have been used for the treatment of acute hepatitis and nonalcoholic fatty liver disease in patients (El-Kamary et al. 2009; Loguercio et al. 2012).

Ursodeoxycholic acid, a hydrophilic stereoisomer of chenodeoxycholic acid, is a major component of Chinese black bear's bile (Ohtsuki et al., 1992). Ursodeoxycholic acid is used to treat chronic cholestatic liver diseases, such as primary biliary cirrhosis and primary sclerosing cholangitis (Chapman 2009; Lindor et al. 2009). Moreover, some evidences indicate that ursodeoxycholic acid decreases the levels of alanine aminotransferase, aspartate aminotransferase, and gamma-glutamyl transpeptidase in patients with chronic hepatitis C and protects livers from against methotrexate-induced toxicity (Omata et al. 2007; Uraz et al. 2008).

Few reports have evaluated the genomic alterations elicited by glycyrrhizin, silymarin, and ursodeoxycholic acid. For examples, *Glycyrrhiza glabra* root extract induces the proliferation of MCF-7 cells by activating extracellular signal-regulated kinases 1/2 and Akt pathways (Dong et al., 2007). Treating hepatocytes with ursodeoxycholic acid shows that ursodeoxycholic acid affects the expression of genes directly involved in cell cycle and apoptotic events, and the E2F-1/p53/apoptotic protease activating factor-1 pathway seems to be the target of ursodeoxycholic acid (Castro et al. 2005). In this study, we treated hepatocytes with non-cytotoxic concentrations of glycyrrhizin, silymarin, and ursodeoxycholic acid, and analyzed the gene expression profiles by microarray. The gene expression profiles were further compared to evaluate the different and the common pathways regulated by these compounds.

Materials and methods

Cell culture

The human hepatoma cell line (HepG2) was obtained from Bioresource Collection and Research Center (Hsinchu, Taiwan). Recombinant HepG2/NF-κB cell, which carried the NF-κB-driven luciferase genes, was constructed as described previously (Hsiang et al. 2009). HepG2 cells and HepG2/NF-κB cells were cultured in Dulbecco's modified Eagle's medium (DMEM) (Life Technologies, Gaithersburg, MD, USA) supplemented with 10% heat-inactivated fetal bovine serum (HyClone, Logan, UT, USA), 100 μg/ml streptomycin, and 100 unit/ml penicillin in a humidified incubator at 37 °C with 5% CO_2.

Chemicals

Glycyrrhizin (purity $\geq$ 95%), silymarin, and ursodeoxycholic acid (purity $\geq$ 99%) were purchased from Sigma (St. Louis, MO, USA), dissolved in dimethyl sulfoxide (DMSO) to a final concentration of 200 mM, and stored at −30 °C. Silymarin (product number 254924) is a mixture of toxifolin (4%), silichristin (27.9%), silidianin (2.9%), silybin A (19.3%), silybin B (31.3%), isosilybin A (8.2%), and isosilybin B (2.3%). MG-132, a NF-κB inhibitor, was purchased from Santa Cruz (Dallas, TX, USA) and dissolved in DMSO to a final concentration of 50 mM. 3-(4,5-Dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) was purchased from Sigma (St. Louis, MO, USA) and dissolved in phosphate-buffered saline (PBS) (137 mM NaCl, 1.4 mM KH_2PO_4, 4.3 mM Na_2HPO_4, 2.7 mM KCl, pH 7.2).

Total RNA isolation

HepG2 cells (2×10^6 cells, passage number 38) were seeded in a 25-cm^2 flask and incubated at 37 °C for 24 h. Cells were then treated with 5 ml of culture medium containing 0.125‰ DMSO (solvent control) or μM hepatoprotectants, and incubated at 37 °C for another 24 h. Total RNA was extracted from cells treated with or without compounds by RNeasy Mini kit (Qiagen, Valencia, CA, USA). Total RNA was quantified using the spectrophotometer (Beckman Coulter, Fullerton, CA, USA) and further evaluated using an Agilent 2100 bioanalyzer (Agilent Technologies, Santa Clara, CA, USA). RNA sample with an RNA integrity number greater than 8.0 was accepted for microarray analysis.

Microarray analysis

Microarray analysis was performed as described previously (Lo et al. 2013; Ho et al. 2014). Briefly, fluorescent RNA targets were prepared from 5 μg of total RNA samples using the MessageAmp™ aRNA kit (Ambion, Austin, TX, USA) and Cy5 dye (Amersham Pharmacia, Piscataway, NJ, USA). Fluorescent targets were hybridized to the Human Whole Genome OneArray™ (Phalanx Biotech Group, Hsinchu, Taiwan). Number of replicates was three. After an overnight hybridization at 50 °C, non-specific targets were washed away and the array was scanned by an Axon 4000 scanner (Molecular Devices, Sunnyvale, CA, USA). Spots with a signal-to-noise ratio $>$ 0 or control probes were selected and normalized by the R program of the limma package (Smyth and Speed 2003). We used surrogate variable analysis (sva) to capture the heterogeneity of expression caused by any variation and to improve the accuracy and reproducibility in analyzing gene expression levels (Leek and Storey 2007). Normalized data were tested by a standard paired *t*-test. The *p*-values were then adjusted for a false discovery rate (FDR) (Benjamini and Hochberg 1995). A value of FDR $<$ 0.5 was considered statistically significant. The fold changes of genes were calculated by dividing the normalized signal intensities of genes in compound-treated cells by those in solvent-treated cells. Genes with fold changes $\geq$ 2.0 or $\leq$ −2.0 and FDR values $<$0.5 were selected as differentially expressed genes and further analyzed by Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway (www.genome.ad.jp/kegg/). We used the Web-based gene set analysis toolkit (bioinfo.vanderbilt.edu/webgestalt/) to test the enriched pathways. Microarray data are minimum information about microarray experiments compliant, and raw data have been deposited in the Gene Expression Omnibus (accession number: GSE67504).

Quantitative real-time polymerase chain reaction (qPCR)

Total RNA was reverse-transcribed for 2 h at 37 °C using High Capacity cDNA Reverse Transcription kit (Applied Biosystems, Foster City, CA, USA). qPCR was performed by mixing cDNA, 2 × Power SYBR Green PCR Master kit and 200 nM of forward and reverse primers. The reaction condition was followed: 10 min at 95 °C; 40 cycles of 15 s at 95 °C and 1 min at 60 °C. Each assay was run on an Applied Biosystems 7300 Real-Time PCR system in triplicates. Relative quantitation (RQ) was calculated using the comparative C_T method ($\Delta\Delta C_T$) which determines the change in expression of a nucleic acid sequence in a test sample (treated group) relative to the same sequence in a calibrator sample (mock group) (Livak and Schmittgen 2001). The ΔC_T value is determined by subtracting the average C_T value of glyceraldehyde-3-phosphate dehydrogenase (GAPDH) gene from the average C_T value of target gene. The $\Delta\Delta C_T$ value is determined by subtracting the ΔC_T value of mock group from the ΔC_T value of treated group. RQ is calculated as $2^{-\Delta\Delta CT}$. Fold changes were further presented as RQ if the RQ value was $\geq$1, or as −1/RQ if the RQ value is $<$1. The primer ser for each gene was followed: histone

deacetylase 9 (HDAC9) forward, 5′-GCAAGAGGAGACAGAGACCG-3′; HDAC9 reverse, 5′-ACTTGGCACTTCACAAGGCT-3′; minichromosome maintenance deficient 3 associated protein (MCM3AP) forward, 5′-CGCTTCCTCTGGTGGTTCTT-3′; MCM3AP reverse, 5′-CTGCACTGCTTGCAAAACCT-3′; GAPDH forward, 5′-TCACCCACACTGTGCCCATCTATGA-3′; GAPDH reverse, 5′-GAGGAAGAGGATGCGGCAGTGG-3′.

Gene interaction network analysis

We constructed three interaction networks of genes with fold changes ≥ 2.0 or ≤ −2.0 in each treatment group using Genomatix Applications software. Then, we merged genes and their interactions in either network into a union network and finally classified this network by GOlorize, a cytoscape plug-in (Garcia et al. 2007). GOlorize first highlighted the nodes that belonged to the same class using color-coding and then constructed an enhanced visualization of the network using a class-directed layout algorithm. Finally, we used Cell Region-Based Rendering and Layout (Cerebral), a cytoscape plug-in, to generate a pathway-like representation of a network. Cerebral uses subcellular localization annotation to create a layered view of a cell, placing nodes in the region corresponding to the appropriate localization (Barsky et al. 2007).

Cell viability assay

HepG2 cells (5×10^6 cells) were cultivated in a 96-well culture plate. After a 24-h incubation at 37 °C, various amounts of glycyrrhizin, silymarin, or ursodeoxycholic acid were added to confluent cell monolayer and incubated for another 24 h. MG-132 (μM), a NF-κB inhibitor, was added to HepG2/NF-κB cells to evaluate the cytotoxicity. Cell viability was monitored by the MTT colorimetric assay as described previously (Cheng et al. 2009). Cell viability (%) was calculated by the equation: (OD of compound-treated cells/OD of solvent-treated cells) × 100.

Luciferase assay

HepG2/NF-κB cells (5×10^6 cells) were cultured in a 96-well culture plate at 37 °C for 24 h, washed with DMEM, and treated with 25 μM of MG-132 or various amounts of glycyrrhizin, silymarin, or ursodeoxycholic acid for another 24 h. Cells were then washed with ice-cold PBS, lysed with 30 μl Triton lysis buffer (50 mM Tris–HCl, 1% Triton X-100, 1 mM dithiothreitol, pH 7.8), and collected with a cell scraper. Luciferase activity was measured as described previously (Cheng et al. 2009). Relative luciferase activity was calculated by dividing the relative luciferase unit (RLU) of compound-treated cells by the RLU of solvent-treated cells.

Statistical analysis

Data were presented as mean ± standard error. Data were analyzed by one-way ANOVA and post hoc Bonferroni test using SPSS Statistics version 20 (IBM, Armonk, NY, USA). A p value less than 0.05 was considered as statistically significant.

Results

Microarray analysis of hepatoprotectant-regulated gene expression

In this study, we chose HepG2 cell, hepatocytes derived from hepatocellular carcinoma, as a cell model to study the gene expression profiles of hepatoprotectants. Cytotoxic studies were first performed. Fig. 1 shows that glycyrrhizin, silymarin, and ursodeoxycholic acid displayed no visible cytotoxic effects at a broad range of concentration (0.5–500 μM). Previous studies indicated that silymarin at 25 μM achieves the highest hepatoprotective effect in FL83B mouse liver cells and at a concentration exceeding 25 μM abruptly increases cell damage in rat hepatocytes (Sainz-Pardo et al. 1994; Lo et al. 2014). In addition, up to 25 μM of glycyrrhizin dose not induce cell death in human epithelial ovarian carcinoma cells (Lee et al. 2010). Therefore, we treated HepG2 cells with 25 μM compounds to analyze novel or common biological pathways regulated by glycyrrhizin, silymarin, and ursodeoxycholic acid in this study.

Microarray data were analyzed by limma and sva packages to examine the differentially expressed genes in cells treated with various hepatoprotectants. We selected genes with fold changes ≥ 2.0 or ≤ −2.0 and FDR values <0.5 as differentially expressed genes for further analysis. Among a total of 30,968 genes, glycyrrhizin, silymarin, and ursodeoxycholic acid downregulated the expression of 777, 684, and 797 genes, respectively. In addition, the expression of 497, 604, and 710 genes was upregulated by glycyrrhizin, silymarin, and ursodeoxycholic acid, respectively. A Venn diagram was used to classify genes those were specific or common in the comparisons. Fig. 1 shows that glycyrrhizin and silymarin affected 145 genes, silymarin and ursodeoxycholic acid affected 196 genes, and glycyrrhizin and ursodeoxycholic acid affected 227 genes. Furthermore, a total of 252 genes was commonly affected by glycyrrhizin, silymarin, and ursodeoxycholic acid.

KEGG pathway analysis of differentially expressed genes altered by three hepatoprotectants

We further analyzed the enriched pathways altered by three hepatoprotectants. Table 1 shows that various KEGG pathways were significantly regulated by glycyrrhizin, silymarin, and ursodeoxycholic acid. No common KEGG pathway was affected by these hepatoprotectants. Glycyrrhizin regulated calcium signaling and T cell receptor signaling pathways, silymarin affected the insulin signaling pathway, and ursodeoxycholic acid affected neuroactive ligand–receptor interaction, tight junction, long-term depression, and extracellular matrix–receptor interaction. Expression levels of genes with p values <0.05 in these pathways are displayed in Table 2.

Interaction network of hepatoprotectant-regulated genes

The relationship between differentially expressed genes affected by each compound was further analyzed by Genomatix Applications software. Genes were correlated based on a review of published data, the Genomatix Knowledge Base, and promoter DNA sequence analysis. Three interaction networks, corresponding to three hepatoprotectants-regulated genes, were constructed. Then, we merged three gene interaction networks using Cytoscape. As shown in Fig. 2, NF-κB was the node in the gene interaction network. A total of 127 genes was affected by all three compounds and associated with NF-κB in this network. The expression profiles of 127 NF-κB-connected genes were then clustered by hierarchical clustering analysis. Fig. 3 shows that genes upregulated by one compound had tendencies of upregulation by other compounds, and vice versa. Among 127 genes, 12 genes with fold changes ≥ 2.0 or ≤ −2.0 were commonly regulated by glycyrrhizin, silymarin, and ursodeoxycholic acid. The gene expression levels of these genes are shown in Table 3. Furthermore, we used Cerebral to generate pathway-like representations of networks for glycyrrhizin, silymarin, and ursodeoxycholic acid treatments. As shown in Fig. 4, these hepatoprotectants affected NF-κB via regulating the same or distinct genes. For example, in the extracellular space, glycyrrhizin modulated NF-κB activity by regulating interleukin 4 (IL4), IL23A, and fibroblast growth factor 10 (FGF10) genes (Fig. 4A), silymarin modulated NF-κB by regulating IL6, IL9, and collagen type 2 alpha 1 (COL2A1) genes (Fig. 4B), and ursodeoxycholic acid affected NF-κB by regulating IL4, IL11, and FGF10 genes (Fig. 4C). In addition, all compounds affected NF-κB

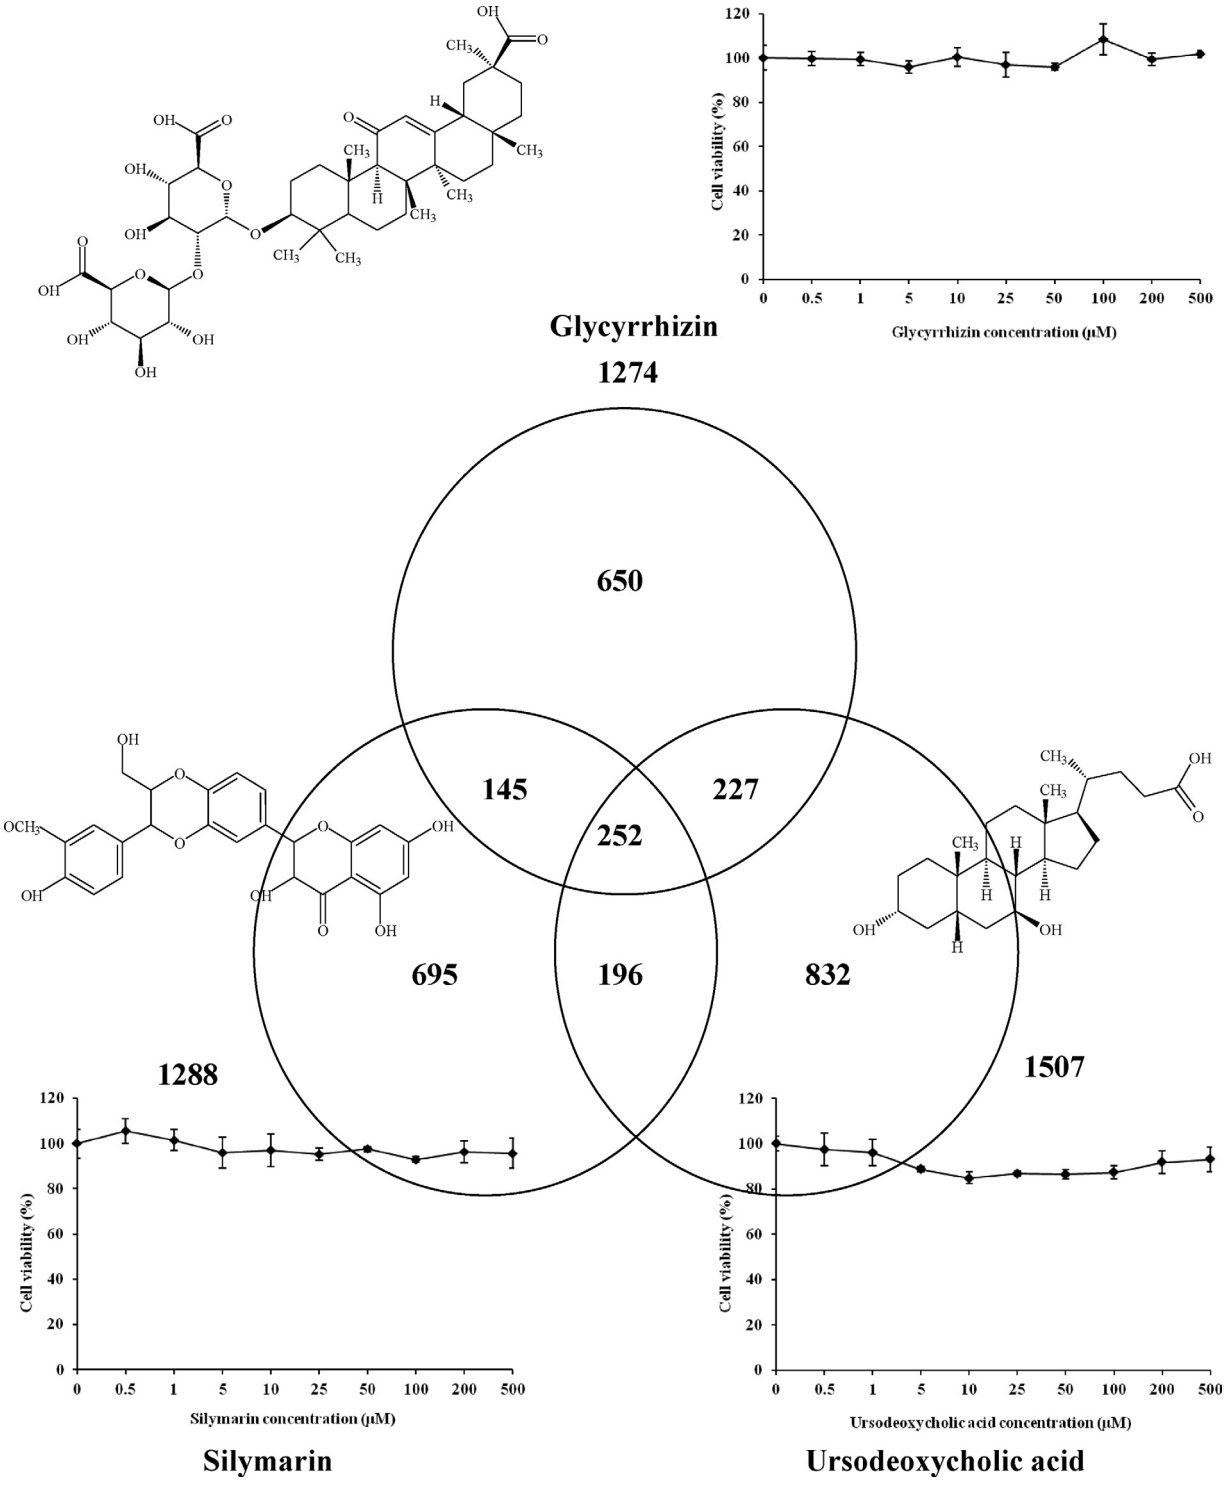

Fig. 1. Venn diagram of differentially expressed genes in HepG2 cells treated with 25 μM glycyrrhizin, silymarin, or ursodeoxycholic acid. The number of genes differentially regulated by glycyrrhizin, silymarin, or ursodeoxycholic acid is shown. Line graphs represent the cell viability of glycyrrhizin-, silymarin-, or ursodeoxycholic acid-treated cells. Values are mean ± standard error of three independent assays.

by regulating HDAC9, MCM3AP, Wilms' tumor 1 (WT1), and Spi-B transcription factor (SPIB) genes in the nucleus.

We further verified microarray data by qPCR. We quantified the expression levels of HDAC9 and MCM3AP genes because these genes are associated with hepatocarcinogenesis and are directly interacted with NF-κB (Wang et al. 2010; Ding et al. 2013). In comparison with mock, the expression of HDAC9 genes was downregulated by glycyrrhizin, silymarin, and ursodeoxycholic acid, with fold changes of −2.08, −11.11, and −3.23, respectively (Table 4). The expression levels of MCM3AP genes were also decreased by glycyrrhizin, silymarin, and ursodeoxycholic acid, with fold changes of −2.56, −1.75, and −2.17, respectively. These findings indicated that the expression of HDAC9 and MCM3AP genes was downregulated by these hepatoprotectants, which were consistent with the findings of microarray data.

Table 1
Classification of genes altered by glycyrrhizin, silymarin, or ursodeoxycholic acid in HepG2 cells by KEGG pathways.

Compound	Pathway	Observed (total)	*p*-value
Glycyrrhizin	Calcium signaling pathway	13 (176)	0.00098
	T cell receptor signaling pathway	8 (93)	0.00416
Silymarin	Insulin signaling pathway	10 (135)	0.00392
Ursodeoxycholic acid	Neuroactive ligand–receptor interaction	22 (254)	0.00037
	Tight junction	10 (136)	0.00496
	Long-term depression	8 (76)	0.00429
	ECM-receptor interaction	8 (87)	0.00679

Table 2
Expression levels of genes which belong to glycyrrhizin-, silymarin-, or ursodeoxycholic acid-altered KEGG pathways in HepG2 cells.

Compound	Gene name	Gene description	Change (folds)	*p*-value
Glycyrrhizin	Calcium signaling pathway			
	ADRA1A	Adrenoceptor alpha 1A	−4.00 ± 1.36	0.0264
	SLC25A4	Solute carrier family 25, member 4	−2.23 ± 0.54	0.0456
	CACNA1E	Calcium channel, voltage-dependent, alpha 1E subunit	2.87 ± 0.72	0.0248
	GRIN2A	Glutamate receptor, ionotropic, *N*-methyl D-aspartate 2A	2.64 ± 0.44	0.0101
	P2RX4	Purinergic receptor P2X, ligand-gated ion channel 4	−3.47 ± 1.25	0.0410
	PPID	Peptidylprolyl isomerase D	−2.22 ± 0.34	0.0144
	T cell receptor signaling pathway			
	CD3Z	CD3Z antigen, zeta polypeptide	−2.17 ± 0.48	0.0384
	IL4	Interleukin 4	2.10 ± 0.36	0.0229
	NRAS	Neuroblastoma RAS viral (v-ras) oncogene homolog	−2.43 ± 0.20	0.0017
	PIK3R1	Phosphoinositide-3-kinase, regulatory subunit 1	−2.36 ± 0.40	0.0151
Silymarin	Insulin signaling pathway			
	PDE3A	Phosphodiesterase 3A, cGMP-inhibited	−2.45 ± 0.34	0.0076
	PRKAB1	Protein kinase, AMP-activated, beta 1 non-catalytic subunit	−4.91 ± 0.56	0.0008
	RPS6	Ribosomal protein S6	2.33 ± 0.45	0.0225
	PRKAG3	Protein kinase, AMP-activated, gamma 3 non-catalytic subunit	−2.22 ± 0.32	0.0112
Ursodeoxycholic acid	Neuroactive ligand–receptor interaction			
	GLRA1	Glycine receptor, alpha 1	3.72 ± 0.75	0.0230
	LEPR	Leptin receptor	2.19 ± 0.30	0.0284
	Long-term depression			
	PPP2CB	Protein phosphatase 2, catalytic subunit, beta isoform	−2.75 ± 0.34	0.0147

Table 3
Expression levels of 12 common NF-κB-connected genes in HepG2 cells responsive to glycyrrhizin, silymarin, and ursodeoxycholic acid treatments.

Gene name	Gene description	Glycyrrhizin		Silymarin		Ursodeoxycholic acid	
		Change (folds)	FDR	Change (folds)	FDR	Change (folds)	FDR
MAP3K7	Mitogen-activated protein kinase kinase kinase 7	−5.98 ± 3.61	0.06	−5.71 ± 3.21	0.05	−4.59 ± 1.83	0.06
HDAC9	Histone deacetylase 9	−3.93 ± 1.24	0.02	−4.92 ± 3.68	0.12	−3.81 ± 0.65	0.02
CFTR	Cystic fibrosis transmembrane conductance regulator	−3.64 ± 1.06	0.02	−2.43 ± 0.91	0.10	−7.41 ± 7.75	0.20
ETHE1	Ethylmalonic encephalopathy 1	−3.07 ± 0.83	0.03	−2.73 ± 0.87	0.05	−3.11 ± 1.47	0.14

UBE2N	Ubiquitin-conjugating enzyme E2N	4.24 ± 1.79	0.04	2.55 ± 1.23	0.15	4.71 ± 0.98	0.02

Effects of hepatoprotectants on NF-κB activities in HepG2 cells

Because NF-κB may play a central role in the glycyrrhizin-, silymarin- and ursodeoxycholic acid-regulated gene network, we wondered whether these compounds were able to affect NF-κB activities. HepG2/NF-κB cells were then treated with various amounts of glycyrrhizin, silymarin, or ursodeoxycholic acid, and the luciferase activity was determined 24 h later. As shown in Fig. 5, MG-132, a well-known proteasome inhibitor that inhibits NF-κB activity by inhibiting IκB degradation, suppressed significantly the NF-κB activity in HepG2 cells. Glycyrrhizin, silymarin, and ursodeoxycholic acid suppressed NF-κB activities in a dose-dependent manner. The EC_{50} value of silymarin on the inhibition of NF-κB activity was 64 ± 9.17 μM, while EC_{50} values of glycyrrhizin and ursodeoxycholic acid were >500 μM. No visible cytotoxic effects were observed. These findings indicate that glycyrrhizin, silymarin, and ursodeoxycholic acid inhibited NF-κB activities in HepG2 cells.

Discussion

In this study, we investigated the gene expression profiles of HepG2 cells in response to glycyrrhizin, silymarin, and ursodeoxycholic acid treatments. Differentially expressed genes were categorized according to KEGG pathways, and we found that hepatoprotectant-regulated genes were associated with various biological pathways. For example, adrenoceptor alpha 1A, glutamate receptor ionotropic *N*-methyl D-aspartate 2A, and purinergic receptor P2X ligand-gated ion channel 4 in calcium signaling pathway,

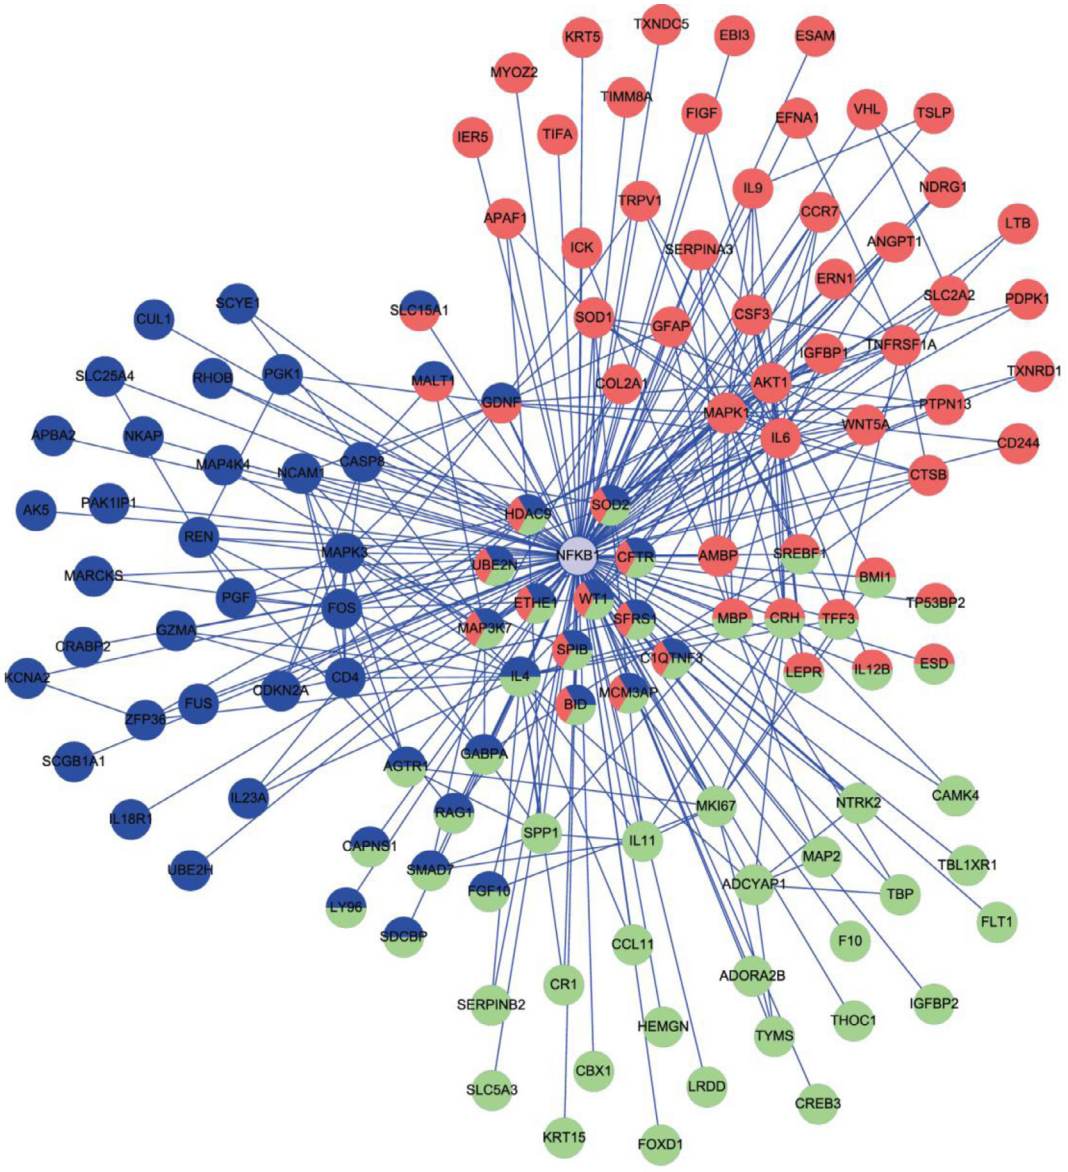

Fig. 2. Network analysis of glycyrrhizin-, silymarin-, and ursodeoxycholic acid-regulated genes in HepG2 cells. Differentially expressed genes, which were affected by either compound, were analyzed by BiblioSphere Pathway Edition software. Then, the network was visualized and classified by cytoscape software. Glycyrrhizin-, silymarin-, and ursodeoxycholic acid-regulated genes are colored in blue, red, and green, respectively. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

Table 4
Expression levels of HDAC9 and MCM3AP genes in glycyrrhizin-, silymarin-, and ursodeoxycholic acid-treated HepG2 cells by qPCR.

Gene	Sample	Avg C_T	Average C_T of GAPDH	ΔC_T[a]	$\Delta\Delta C_T$[b]	Change (folds)[c]
HDAC9	Glycyrrhizin	26.47 ± 0.06	30.04 ± 0.01	−3.41 ± 0.17	1.05 ± 0.17	−2.08
	Silymarin	37.07 ± 1.07	30.13 ± 0.03	6.94 ± 1.07	3.48 ± 1.07	−11.11
	Ursodeoxycholic acid	27.37 ± 0.13	30.13 ± 0.03	−2.76 ± 0.13	1.70 ± 0.13	−3.23
MCM3AP	Glycyrrhizin	33.89 ± 1.06	30.04 ± 0.01	4.00 ± 1.07	1.36 ± 1.07	−2.56
	Silymarin	33.52 ± 1.19	30.07 ± 0.01	3.44 ± 1.19	0.81 ± 1.19	−1.75
	Ursodeoxycholic acid	33.90 ± 1.06	30.13 ± 0.03	3.77 ± 1.06	1.13 ± 1.06	−2.17

[a] The ΔC_T value is determined by subtracting the average C_T value of GAPDH gene from the average C_T value of target gene. The standard deviation of the difference is calculated from the standard deviations of the target gene and GAPDH gene.

[b] The $\Delta\Delta C_T$ value is determined by subtracting the ΔC_T value of mock group from the ΔC_T value of treated group. This is a subtraction of an arbitrary constant, so the standard deviation of $\Delta\Delta$CT is the same as the standard deviation of ΔC_T value.

[c] RQ is calculated as $2^{-\Delta\Delta CT}$. Fold changes were presented as RQ if the RQ value was ≥1, and as −1/RQ if the RQ value is <1.

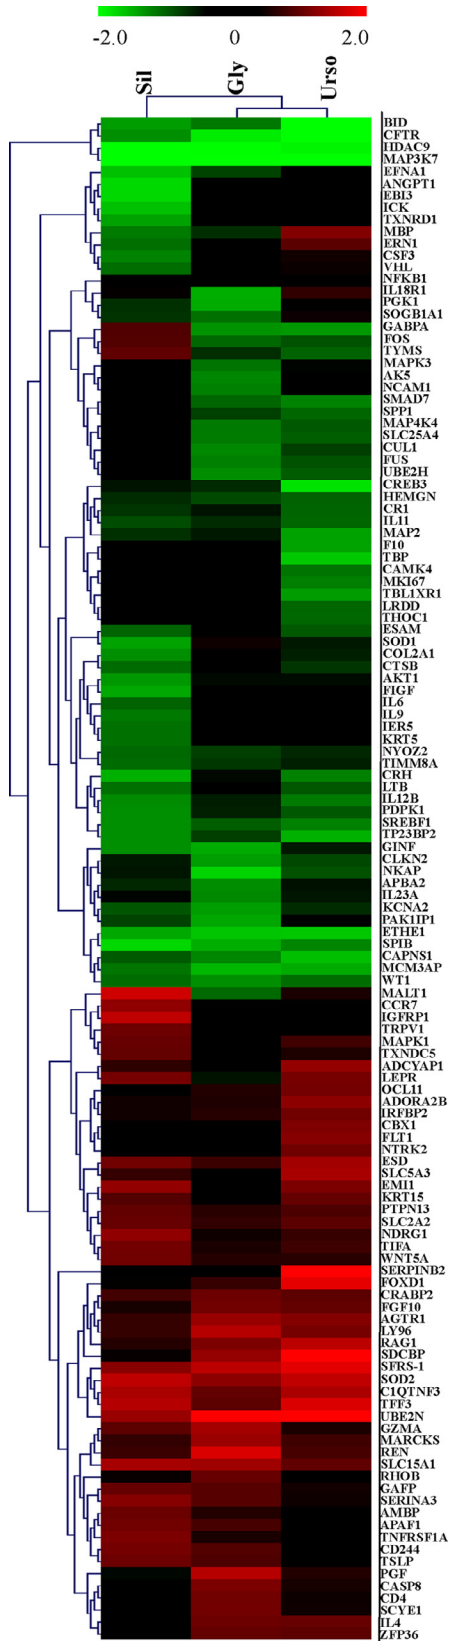

Fig. 3. Hierarchical clustering analysis of 127 NF-κB-connected genes affected by either glycyrrhizin (Gly), silymarin (Sil), or ursodeoxycholic acid (Urso). Normalized $\log_2$ expression values are color-coded according to the legend on the top. Increased levels are colored red and decreased levels are colored green. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

and glycine receptor alpha 1 and leptin receptor in neuroactive ligand–receptor interaction mediate actions in the nervous system through the binding of different neurotransmitters (Betz et al. 1999; Koshimizu et al. 2003; Vial et al. 2004; Ryan et al. 2008). Neuroblastoma RAS viral oncogene homolog and phosphoinositide-3-kinase regulatory subunit 1 in T cell receptor signaling pathway are also involved in insulin signaling pathway (Saltiel and Kahn 2001). Protein kinase AMP-activated beta 1 (PRKAB1) and PRKAG3 are known to be associated with lipogenesis (Bailey 2007). Based on these results, we suggested that these hepatoprotectants might regulate pathways involved in neurotransmission, and glucose and lipid metabolism in liver.

We further investigated differentially expressed genes by gene interaction network analysis. We found that NF-κB seemed to be in the central part of the network and 127 genes were connected directly to NF-κB. Furthermore, we found that 12 NF-κB-connected genes were differentially expressed in all three compound treatments. Among them, HDAC9, MCM3AP, SPIB, WT1, ethylmalonic encephalopathy 1 (ETHE1), BH3 interacting domain death agonist (BID), superoxide dismutase 2 (SOD2), and mitogen-activated protein kinase kinase kinase 7 (MAP3K7) genes are known to be involved in hepatocarcinogenesis, apoptosis, and anti-oxidative pathways, and their expressions are directly regulated by NF-κB. For examples, HDAC9 is a transcriptional regulator of the histone deacetylase family, which is regulated by Sp1 and NF-κB (Ma et al. 2011). Recent study indicated that HDAC9 promotes hepatocellular carcinoma progression by inhibiting p53 transcriptional activity (Ding et al. 2013). MCM3AP is an acetyltransferase that acetylases MCM3, and plays a role in DNA replication (Takei et al. 2001). It is also a novel hepatitis B virus integration site, and upregulation of MCM3AP promotes the hepatocarcinogenesis by affecting flanking sequences (Wang et al. 2010). SPIB is a transcription factor that binds to a purine-rich sequence of promoters (Bonadies et al. 2010). Using a random-walk-based community detection algorithm, Petrochilos et al. (2013) have identified that SPIB is functionally related to cancer and shows a promise as a therapeutic target. WT1 encodes a transcription factor involved in cell growth and development. The presence of NF-κB-responsive elements in the promoter of WT1 gene suggests that the transcription of WT1 gene is regulated by NF-κB pathway (Dehbi et al. 1998). WT1 is expressed in a substantial proportion of hepatocellular carcinoma contributing to tumor progression and resistance to chemotherapy, suggesting that WT1 may be an important target for liver cancer treatment (Perugorria et al. 2009). ETHE1 gene accelerates the export of NF-κB from nucleus and inhibits p53-dependent apoptosis, thus contributing to hepatocarcinogenesis (Higashitsuji et al. 2002). In our study, all three compounds reduced the expressions of HDAC9, MCM3AP, SPIB, WT1, and ETHE1 genes at non-toxic concentrations in hepatocytes, suggesting the anticancer potentials of these compounds.

In addition to ETHE1, BID gene product is a specific proximal substrate of caspase-8 in the Fas apoptotic signaling pathway (Li et al. 1998). While full-length BID is localized in cytosol, truncated BID (tBID) translocates to mitochondria and thus transduces apoptotic signals from cytoplasmic membrane to mitochondria. The SOD2 gene encodes an intramitochondrial free radical scavenging enzyme, the first line of defense against superoxide produced by oxidative phosphorylation. SOD2 maintains the integrity of mitochondrial enzymes that are inactivated by superoxide (Li et al. 1995). SOD2 and tBID are known to be associated with apoptosis via a mitochondrial pathway (Yin 2000; Pardo et al. 2006). The ability of glycyrrhizin, silymarin, and ursodeoxycholic acid to reduce BID or induce SOD2 may protect HepG2 cells from damage by suppressing apoptosis via the mitochondrial pathway.

MAP3K7 is linked to IL1 receptor and tumor necrosis factor (TNF) receptor signalings (Sato et al. 2005). MAP3K7 is activated by

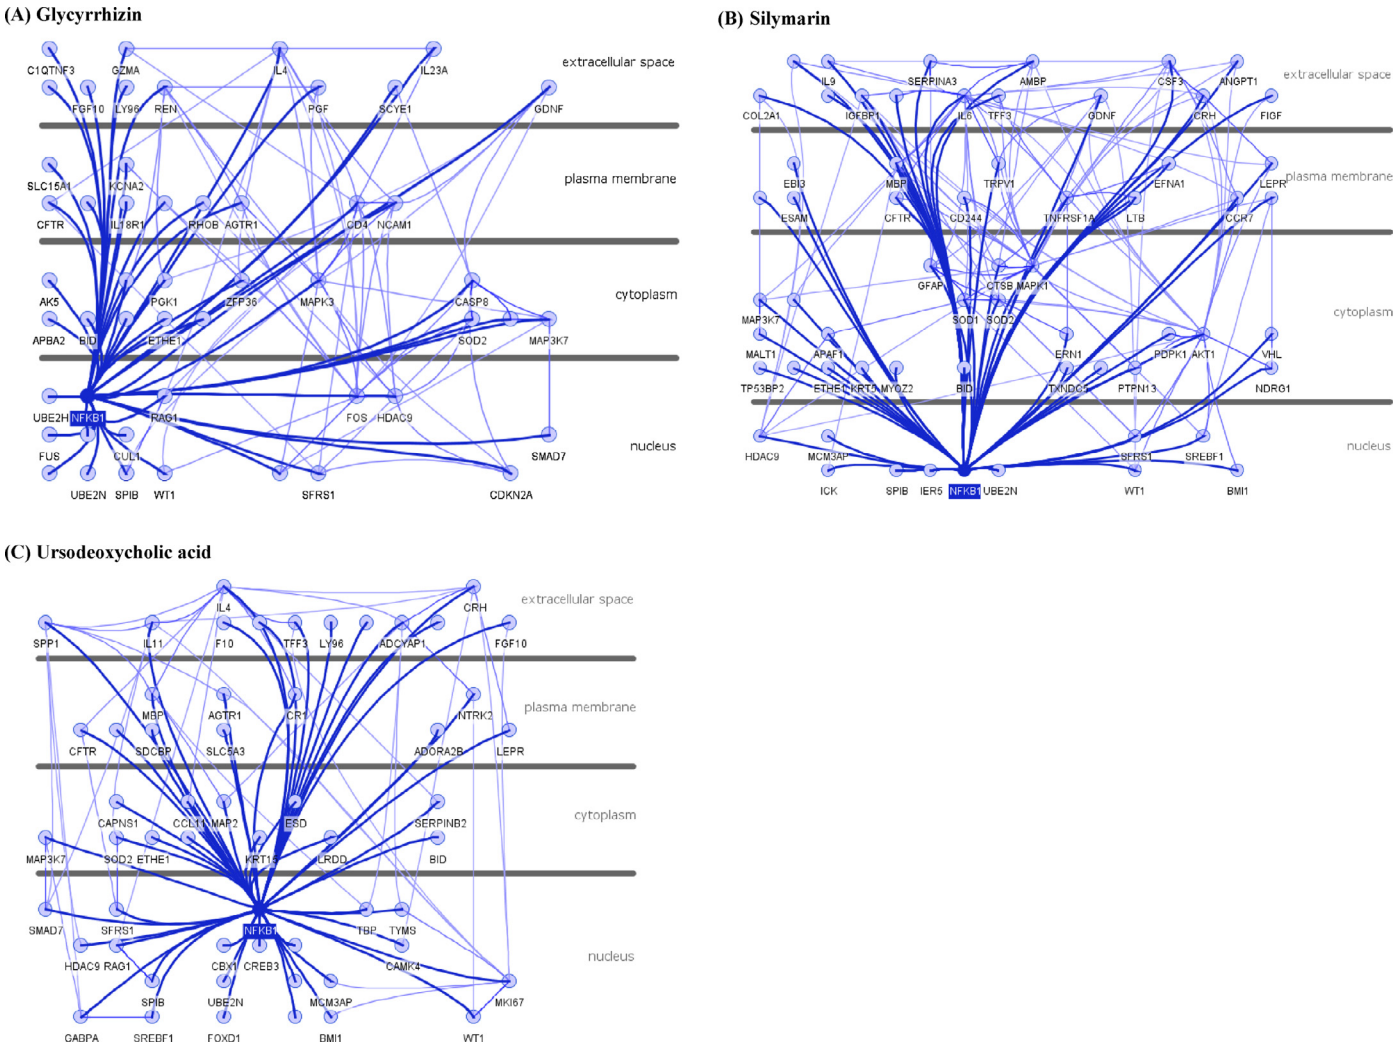

Fig. 4. Cerebral layouts generated by cytoscape plug-in illustrate the pathway-like representations of networks for glycyrrhizin (A), silymarin (B), and ursodeoxycholic acid (C) treatments in HepG2 cells.

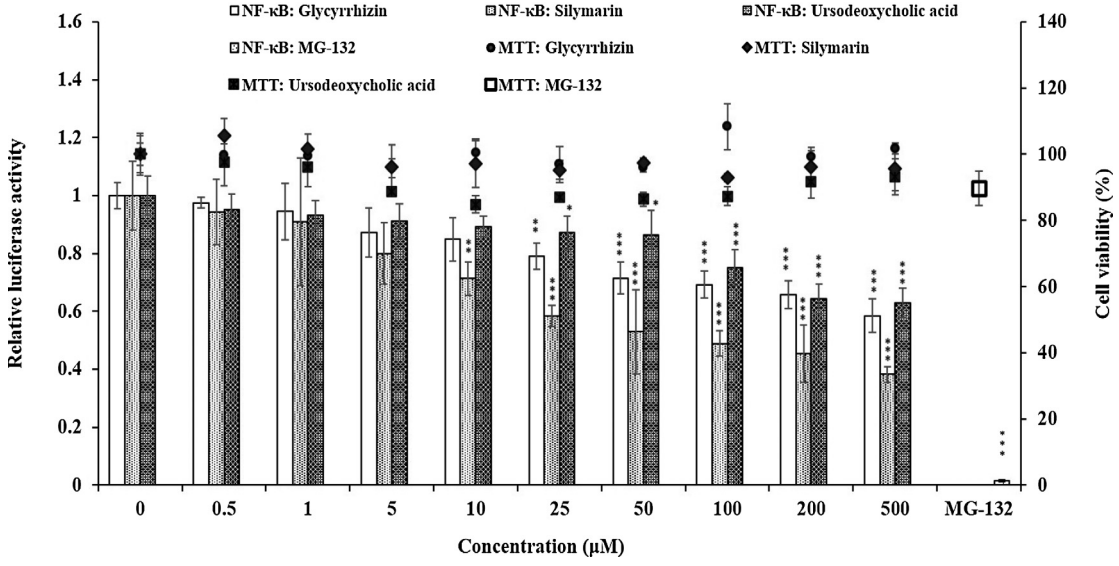

Fig. 5. Inhibitory effects of glycyrrhizin, silymarin, and ursodeoxycholic acid on NF-κB activities in HepG2 cells. HepG2/ NF-κB cells were seeded into 96-well plates and treated with 25 μM of MG-132 or various amounts of glycyrrhizin, silymarin and ursodeoxycholic acid. Luciferase activity and cell viability were determined at 24 h. The bars represent the relative luciferase activity, which is presented as comparison with the RLU relative to solvent-treated cells. The spots represent the cell viability during treatment. Values are mean ± standard error of three independent assays. $^{*}p < 0.05$, $^{**}p < 0.01$, $^{***}p < 0.001$, compared with mock.

chemical and physical stresses and regulates stress-induced activation of activator protein-1 and NF-κB (Ishitani et al. 2003; Takaesu et al. 2003; Shim et al. 2005). Hypoxia-activated MAP3K7 results in the activation of c-Jun-dependent transcription in response to oxidative stress (Blanco et al. 2007). In addition, BID is also able to induce the generation of reactive oxygen species (ROS) following death receptor activation (Ding et al. 2004). However, SOD2 plays a critical cytoprotective role against oxidative stress (Delhalle et al. 2002). In this study, the up-regulation of SOD2 and the down-regulation of BID and TAK1 by glycyrrhizin, silymarin, and ursodeoxycholic acid suggested the anti-oxidative properties of these compounds.

Hepatocytes exposed to BID siRNA are resistant to Fas and TNF-α-induced cell death (Yin et al. 1999; Guicciardi et al. 2005). Treatment of lymph-proliferative mice with BID antisense also ameliorates liver injury following bile duct ligation (Higuchi et al. 2001). Additionally, overexpression of SOD2 is effective against mitochondrial oxidative stress in hepatocytes and is protective against alcohol-induced liver injury in an enteral feeding rat model (Wheeler et al. 2001). The up-regulation of SOD2 in hepatocytes is associated with a reduction of ROS-induced injury after ischemia-reperfusion (Chen et al. 2006). Dominant-negative MAP3K7 induces G0 exit in the quiescent liver and accelerates hepatic cell cycle progression during regeneration (Bradham et al. 2001). Moreover, the inhibition of MAP3K7/c-Jun N-terminal kinase decreases the proliferation of hepatic stellate cells, a critical effector in hepatic fibrogenesis (Schnabl et al. 2001). Therefore, the differential expression of BID, SOD2, and TAK1 genes by glycyrrhizin, silymarin, and ursodeoxycholic acid suggested the hepatoprotective effects in livers.

NF-κB signaling pathways have a central function in the regulation of inflammation–fibrosis–cancer axis. NF-κB activation is crucially involved both in the fibrogenesis and in the initiation and promotion of liver cancers (Sun and Karin 2008; Luedde and Schwabe 2011). However, the dual role of NF-κB activation in hepatocarcinogenesis indicates that activation of NF-κB not only displays beneficial effects but also suppresses the viability of hepatocytes. For examples, in the early stages of tumorigenesis, NF-κB activation prevents the death of hepatocytes and thus avoids the release of proinflammatory cytokines by necrotic hepatocytes. However, in the late stages of tumorigenesis, NF-κB activation promotes the survival of transformed hepatocytes and elicits the malignancy of liver cancers (Sun and Karin 2008; Luedde and Schwabe 2011). Glycyrrhizin, silymarin, and ursodeoxycholic acid inhibited NF-κB activities in HepG2 cells, a human hepatoblastoma cell line, suggesting that glycyrrhizin, silymarin, and ursodeoxycholic acid might exhibit hepatoprotective effects by altering the survival of hepatoblastoma cells. Moreover, this finding was also consistent with previous reports that indicate glycyrrhizin, silymarin, and ursodeoxycholic acid play important roles in the treatment of hepatocellular carcinoma by reducing tumor cell proliferation or reducing the angiogenesis of liver (Kuiper et al. 2010; Li et al. 2014; Mastron et al. 2015).

In conclusions, this study demonstrated that different hepatoprotectants regulated different biological pathways. However, these hepatoprotectants also regulated the expression of common genes through a central molecule, NF-κB. Moreover, non-toxic dosages of hepatoprotectants inhibited NF-κB activities. Because the genes regulated by hepatoprotectants are relevant to antioxidant or anti-apoptotic pathways, we proposed that these compounds exerted their hepatoprotective effects by regulating apoptosis and oxidative stress in hepatocarcinoma cells.

Conflict of interest

There was no conflict of interest.

Abstract

Cadmium chloride at concentrations of 10–50 mM and acetaldehyde (AA) at 1–5 mM showed synergistic toxic effects on V79 cells in vitro. Furthermore, synergistic effects of these chemicals were also observed in mutagenicities of the *Hprt* gene within certain dose ranges (cadmium chloride 5–10 mM, and AA 1–2.5 mM). Moreover, lipid peroxide formation, malondialdehyde (MDA) formation, detected by 2-thiobarbituric acid (TBA) reaction and the mitochondrial membrane potentials detected by rhodamine 123 uptake were significantly increased with the combined effect of cadmium and AA in V79. Thus, the cytotoxicity and genotoxicity displayed by combination of these chemicals can be considered to be associated with oxidative stress. Further, these effects were efficiently reduced by quercetin and less efficiently with glycyrrhizin.

Keywords: Quercetin; Glycyrrhizin; Cadmium; *Hprt*; Genotoxicity

1. Introduction

Cadmium, one of the most potent hazard inorganic substances in our environment, has been found to have severe toxic and genotoxic effect in animal both in vivo and in vitro system, and even in human as well [1–8]. In addition, human exposure to acetaldehyde (AA) is widespread and occurs regularly. The principal routes of direct exposure to AA are gastrointestinal and inhalation. AA exposure also exists endogenously as a primary metabolite of ethanol oxidation, and thus, alcohol consumption is an additional risk factor in conjunction with exogenous sources of environmental and occupational exposures to AA [9]. AA has been proposed that the mutagenic, carcinogenic and teratogenic effect of ethanol be mediated via this metabolite [10]. Thus, humans are exposed to various environmental hazardous substances, the effect of the toxic chemical in human lymphocytes, such as cytotoxicity and genotoxicity, has currently been concerned [11–15]. Oxidative stress is one of the main causes of cytotoxicity or genotoxicity. Thus, the oxidative stress is considered to be associated with many diseases, for example aging, cardiovascular disease, and cancer [16–18]. An important etiological mechanism of these diseases may be a causal relationship between the presence of oxidants and the generation of lipid hydroperoxides. These hydroperoxides can decompose to alkoxy-($RO^{\bullet}$) and peroxy-($ROO^{\bullet}$) free radicals that can oxidize other cell components,

resulting in changes in enzyme activity or the generation of mediators (i.e. malondialdehyde (MDA) and reactive oxygen species (ROS)) that can cause a mitochondrial depolarization or further cell damage [19]. Therefore, the formation of MDA or uptake of rhodamine 123 is considered as an index of lipid peroxidation that bring cells injury.

On the other hand, amongst the most common of Asiatic folk medicine glycyrrhizin is acted as an anti-inflammatory agent on neutrophil functions including ROS generation [20]. Thus, glycyrrhizin can be considered as a quenching agent of free radicals and a blocking agent of lipid peroxidation chain reactions. Furthermore, the average daily intake of major flavonols, such as quercetin, myricetin and kaempherol, is in an amount of around 16 mg/day [21]. Quercetin is a highly effective antioxidant that has been shown to inhibit free radical mediated damage of low-density lipoproteins in vitro [22,23]. Moreover, the abilities of quercetin to scavenge free radicals and block lipid peroxidation were tested by Formica et al. against cardiovascular disease [24,25].

In the present study, we report herein that the combined effect of cadmium and AA on cytotoxicity or genotoxicity was studied in V79 cells. In addition we examined effect of these chemicals on the formation of lipid peroxides by detecting by 2-thiobarbituric acid (TBA) reaction, and on the cell injuries due to lipid peroxidations by measuring rhodamine 123 uptake. Further, we examined effects of natural antioxidants, quercetin and an Asiatic folk medicine, glycyrrhizin by co-exposure with these toxic agents on various biological markers for toxicities in V79.

2. Material and methods

2.1. Chemicals

Quercetin, glycyrrhizin, $CdCl_2$, MEM, penicillin–streptomycin, trypsin–EDTA, 6-thioguanine (6-TG), dulbeccols phosphate buffered saline (PBS), EMS, TBA, MTT were purchased from SIGMA company (St. Louis, USA). Chinese hamster lung cells were obtained from Professor Ruey-Hseng Lin, Chung Shan Medical and Dental College at Taichung in Taiwan. AA and solvents (Merck, Darmstadt, Germany) and other reagents or dishes (Nunc, Denmark) were obtained from the indicated suppliers.

2.2. Cell growth

V79 cells from lung fibroblasts of Chinese hamster were grown on a monolayer in using MEM medium supplemented with 10% fetal bovine serum (FBS), penicillin (100 U/ml) and streptomycin (100 mg/ml) at 75 cm^2 flask. Under the incubation condition with 5% CO_2 in humidified air at 37°C, the cells have a generation time of about 12 h.

2.3. Microculture tetrazolium (MTT) assay

V79 cells in triplicate (three wells) were plated into a series of 24-well culture plates (1 ml culture/well) at a cell density of 5×10^4 cells/ml. Following a 18 h incubation at 37°C, 5% CO_2, 100% relative humidity, MEM medium was removed and washed with PBS. A volume of 1 ml culture medium containing drug was dispensed within appropriate wells.

According to Alley et al. method with a MTT assay [26], the combined effect of cadmium and AA on the growth of V79 cells was performed. Cell cultures were incubated at 37°C in 5% CO_2 humidified atmosphere for 2–18 h. Cell line growth and growth inhibition were measured at 563 nm with a scanning spectrophotometer (Shimadzu UV-260). Briefly, the V79 cells at a density of 5×10^4 cells/dish were treated with cadmium and/or AA at various concentrations. After a 2–18 h incubation, medium was replaced by the one containing 100 μl MTT (5 mg/ml) with PBS washing in between. The cells were incubated for another 4 h, then the blue crystals that are the metabolized product of MTT were extracted by isopropanol. Absorbence at 563 nm was determined and used for the measurement of the proportion of surviving cells.

2.4. Colony efficiency assay

V79 cells were seeded at 200 cells/flask (25 cm^2). After a 18 h incubation, the medium was removed and washed twice with PBS solution. Cells were exposed to the indicated doses of drug for 4 h. Subsequently, fresh drug-free culture medium was added and after 7 days incubation, the cultures were fixed and stained. The mean colony-forming efficiency was determined

from triplicate flasks and based on colonies each containing at least 50 cells.

2.5. Mutants in the Hprt gene

The mutagenicity of drugs was determined by the replating method [27]. V79 cells were incubated in MEM medium containing hypoxanthinine, aminopterin, and thymidine (HAT). After 3 days, the cells were replated at 1×10^6 cells/75 cm^2 flask and incubated for 18 h. Then the medium were removed and washed twice with PBS. Fresh MEM culture medium, culture medium containing drug was added and incubated for 4 h at 37°C and 5% CO_2 in comparison with treated methanesulfonic acid ethyl ester (EMS) as the positive control. Subsequently, drug culture medium was removed and washed twice with PBS, and then the cells were dissociated by treatment with trypsin–EDTA. A total of 2×10^5 cells were replated each at 9 cm^2 dish in five plates with MEM medium for 3 days. Subcultures at 2×10^5 cells/9 cm^2 dish for 4 days, and 2×10^5 cells were replated again each at 9 cm^2 dish in five plates in medium containing 10 mg/ml 6-TG. Following 7 or 8 days incubation, the 6-TG-resistant mutant colonies formed were fixed, stained, and counted.

On the other experiment, cell survival immediately post mutagen treatment was independently determined after 7 days incubation (200 cells/50 mm dish) in MEM without selective agents. Colonies were counted by mutant frequencies estimated.

2.6. Lipid peroxidation assay

Following Yagi's method, the lipid peroxide level was determined by fluorometric measurement after reaction with TBA [28]. The level is expressed in term of malondialdehe (MDA) as standard.

The scraped cells were resuspended in 50 mM phosphate buffer, and divided into two parts. One part was used for the estimation of lipid peroxidation by MDA–TBA formation. The cells were added and mixed with 3% sodium dodecyl sulfate (SDS), 0.1 N HCl, 10% phosphotungastic acid, and 0.7% TBA, and the reaction mixture was heated at 95°C in dark for 10 min. After cooling, *n*-butanol was added and the mixture was shaken vigorously and centrifuged at 3000 rpm for 10 min. The supernatant was determined with fluorometer (Ex/Em = 515/555 nm) in comparison to 1,1,3,3-tetramethoxypropane standards in an identical buffer. The other part was centrifuged at 10 000*g* for 15 min, the protein free lysate was obtained. Proteins were measured with a commercial kit (Bio-Rad) using bovine serum albumin as the standard.

2.7. Mitochondrial membrane potential

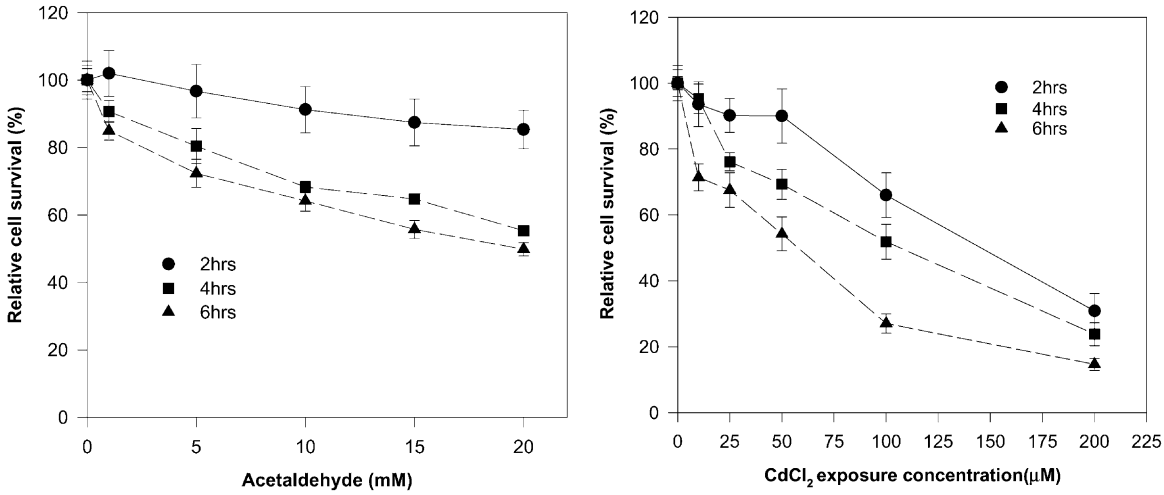
According to Lemasters and co-workers method, changes in mitochondrial membrane potential were evaluated from uptake of rhodamine 123 [29]. V79 cells (1×10^6 cells/25 cm^2 flask) were incubated with 1 μM rhodamine 123 at 37°C. Following 30 min incubation, the various concentration of drug was dispensed within appropriate flasks. After 4 h time, the MEM medium was removed and washed with PBS buffer. The cells (1×10^6) were suspended in PBS containing 0.1% Triton X-100. Standing 10 min, the samples were centrifuged (6000*g*), and rhodamine 123 concentration in the supernatant was determined with a Sequoia–Turner fluorometer at excitation and emission wavelengths of 490 and 515 nm in comparison to rhodamine 123 standards in an identical buffer.

2.8. Statistical analysis

The results are reported as means ± S.D. from individual determinations. Statistical differences were analyzed according to Student's *t*-test; significant differences were established at $P < 0.05$.

3. Results

Effects of cadmium and AA on cell survivals are shown in Fig. 1a and b. Treatment with 10–200 μM cadmium and 1–20 mM AA alone reduced survivals below the control ($P < 0.05$). For the combined effect of cytotoxicity between cadmium and AA, we examined on the co-exposure to V79 cells at the dosage of the concentration 10, 25, 50 μM cadmium and 1, 5 mM AA because both retain cell viability above 50% compared to the control cell, respectively. The results exhibited synergistic cytotoxicity of co-exposure of cadmium and AA on V79 cells for treatment in 4 h



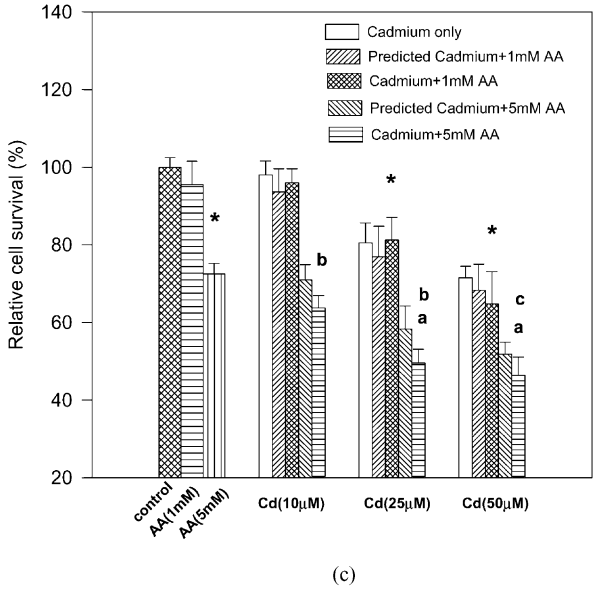


Fig. 1. (a) Effect of AA on survivals of V79 cells. The survivals were determined by MTT assay at 2, 4, and 6 h after addition of AA, in quadruplicate. (b) Effect of cadmium on survivals of V79 cells. The survivals were determined by MTT assay at 2, 4, and 6 h after addition of cadmium, in quadruplicate. (c) Effect of cadmium (Cd) and AA (acetaldehyde) on survivals of V79 cells. The survivals were determined by MTT assay at 4 h after addition of Cd and AA, in quadruplicate. (∗): compared with control ($P < 0.05$); (a): compared with AA ($P < 0.01$); (b, c): compared with Cd (b: $P < 0.01$, c: $P < 0.05$).

interval using MTT assay (Fig. 1c). The cell growth of V79 cells was inhibited by 36, 51, and 56% observed mortality at the concentration 10, 25, 50 μM cadmium and 5 mM AA, respectively.

After our evaluation of the acute toxicity, we focused on the chronic toxicity of co-exposure of cadmium and AA by colony assay. Similarly, we first assessed the cytotoxicities of cadmium and AA on

Table 1
Effect of cadmium ($CdCl_2$) and acetaldehyde (AA) on survivals of V79 cells by colony assay, in triplicate

Dose of $CdCl_2$ (μM)	Relative cell survival (%)

* $P < 0.05$.
** $P < 0.01$ (compared with control).

V79 cells for treatment in 4 h interval, and subsequently allowed damage cells growing for 7 days to form colony. The results were shown on the Table 1, however, the mean percentage survival ($P < 0.01$) of cells exposed to 5 mM AA was 19% compared with control. Thus, of the substances and concentration we tested on the co-exposure to V79 cell at the concentration 5, 10, 15 μM cadmium and 1, 2.5 mM AA, respectively. The result, based upon a model of independent joint action [30], was shown on the Table 2. Obviously, it showed that the percentage of observed mortality is twice time more than that of predicted mortality except 5 μM cadmium. For example, treatment with both 10, 15 μM cadmium and 1, 2.5 mM AA was exhibited by 23, 54, 64, and 89% observed mortality, respectively. Thus, it indicated that the combined chronic cytotoxicity of cadmium and AA be synergistic effect on V79 cells by colony assay.

We further studied the mutagenic with combination effects of cadmium and AA on V79 cells, and compared the effects of cadmium alone and in combination with AA in a subtoxic or low mutagenic concentration. As shown in Table 3, it observed mutagenesis assay at *Hprt* gene was similar result to cytotoxicities. It showed that mutant at dose 5–15 μM cadmium and 2.5 mM AA was counted by plating efficiency frequency with 34, 7, 3%, respectively, in contrast to positive control EMS (93%). On the other hand, 11, 18, and 14 clones (EMS 173) were determined mutant cells by colony treated 6-TG. The results also assessed that observed mutant in comparison with predicted mutant is synergistic interaction of cadmium and AA on V79 cells by colony assay (Table 4).

Accordingly, Yagi's method [28] lipid peroxidation can be assayed by determining the rate of production of TBA-reactive components, which can be expressed

Table 2
Comparison of observed and predicted mortality induced by AA and cadmium on V79 cells by colony assay[a]

Dose	Observed relative mortality (%)	Predicted relative mortality (%)	Interaction
1 mM AA + 5 μM $CdCl_2$	3.1 ± ND	3.3 ± ND	+
1 mM AA + 10 μM $CdCl_2$	22.6 ± 4.9	8.2 ± ND	>+
1 mM AA + 15 μM $CdCl_2$	53.6 ± 6.9	20.9 ± 9.6	>+
2.5 mM AA + 5 μM $CdCl_2$	31.5 ± 6.1	25.6 ± 4.5	+
2.5 mM AA + 10 μM $CdCl_2$	63.8 ± 2.0	29.4 ± 4.7	>+
2.5 mM AA + 15 μM $CdCl_2$	88.5 ± 3.5	39.1 ± 4.1	>+

[a] Independent joint action model: $P(M) = P(A) + P(B) - P(AB)$. ND: non-detectable response; (+): additive; (>+): synergistic; AA: acetaldehyde; $P < 0.05$.

Table 3
Effect of cadmium and AA on *Hprt* mutant frequencies of V79 cells in V79 cells by colony assay, each dose has been performed in 10 experiments for collecting enough mutant cells[a]

Dose	Plating efficiency (%)	Mutant cells (numbers/10^6 cells)
Control	100.0 ± 3.9	0
5 μM $CdCl_2$	84.4 ± 4.7	0
10 μM $CdCl_2$	46.8 ± 5.4**	4
15 μM $CdCl_2$	30.2 ± 3.9**	2
2.5 mM AA	71.9 ± 5.0*	3
2.5 mM AA + 5 μM $CdCl_2$	34.2 ± 2.1[a]	11
2.5 mM AA + 10 μM $CdCl_2$	7.1 ± 1.0[a]	18
2.5 mM AA + 15 μM $CdCl_2$	2.7 ± 0.6[a]	14
600 μg/ml EMS	93.2 ± 1.6	173

[a] Compared with AA or $CdCl_2$ ($P < 0.01$); AA: acetaldehyde.
* $P < 0.05$ (compared with control).
** $P < 0.01$ (compared with control).

Table 4
Comparison of observed and predicted mutant frequency induced by AA and cadmium[a]

Dose	Observed mutant frequency (1×10^6)	Predicted mutant frequency (1×10^6)	Interaction
2.5 mM AA + 5 μM $CdCl_2$	11	3	>+
2.5 mM AA + 10 μM $CdCl_2$	18	7	>+
2.5 mM AA + 15 μM $CdCl_2$	14	5	>+

[a] $N(AB) = N(A) + N(B) - N(C)$ (independent joint action model): $N(AB)$, number of observed mutant; $N(A) + N(B) - N(C)$, number of predicted mutant; $N(A)$, number of A mutant; $N(B)$, number of B mutant; $N(C)$, number of control mutant; >+, synergistic; AA, acetaldehyde.

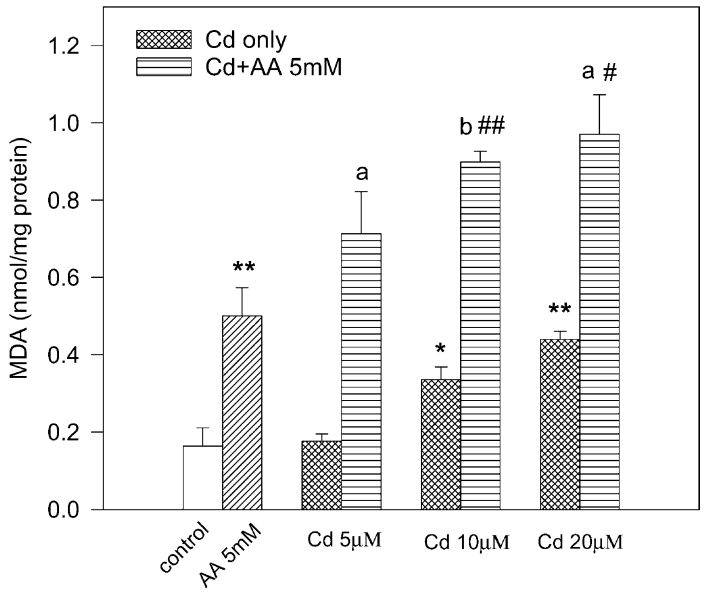

Fig. 2. Effect of cadmium and AA on lipid peroxidation in V79 cells, in triplicate. (∗, ∗∗): compared with control (∗: $P < 0.05$, ∗∗: $P < 0.01$); (#, ##): compared with AA (#: $P < 0.05$, ##: $P < 0.01$); (a, b): compared with Cd (a: $P < 0.05$, b: $P < 0.01$).

Table 5
Comparison of observed and predicted mortality on V79 cells by lipid peroxidation assay[a]

Dose	Observed relative mortality (nmol/mg)	Predicted relative mortality (nmol/mg)	Interaction
5 mM AA + 5 μM $CdCl_2$	0.71 ± 0.17	0.51 ± 0.07	>+
5 mM AA + 10 μM $CdCl_2$	0.90 ± 0.03	0.67 ± 0.08	>+
5 mM AA + 20 μM $CdCl_2$	0.97 ± 0.12	0.78 ± 0.07	>+

[a] $N(AB) = N(A) + N(B) - N(C)$ (independent joint action model): $N(AB)$, amount of observed MDA; $N(A) + N(B) - N(C)$, amount of predicted MDA; $N(A)$, amount of A MDA; $N(B)$, amount of B MDA; $N(C)$, amount of control MDA; >+, synergistic; AA, acetaldehyde.

as MDA equivalents. The results were expressed at the lipid peroxidation on the growth of V79 cells when treatment with 5–20 μM cadmium and 5 mM AA (Fig. 2). For example, cadmium induced the MDA formation in a dose-dependent manner, and the results showed a synergistic increase MDA production by 0.2 nmol/mg protein (Table 5). Furthermore, several groups [31–35] reported that mitochondria are a primary target of toxic injury and that their dysfunction ultimately leads to plasma membrane damage or cell death. For our investigation, mitochondria function was affected from uptake of rhodamine 123 in significant enhancement (200%) in >10 μM cadmium and 5 mM AA treated cells, while a few increment was found in 5 mM cadmium treated (Fig. 3).

As above described, glycyrrhizin and quercetin are acted as good antioxidant agents. To investigate the antioxidant activity of glycyrrhizin and quercetin as anti-carcinogenic agents, we first examined the cytotoxicities of the exposure to 10–500 μM glycyrrhizin or 5–80 μM quercetin alone on V79 cells, both drugs retain cell viability above 80% compared to the control cell by MTT assay. Furthermore, treatment with 10 and 20 μM quercetin was increased by the inhibition of lipid peroxidation in 15 and 20%, respectively (Fig. 4), but not treatment with 50–200 μM glycyrrhizin. Finally, 5–20 μM quercetin and 50–200 μM glycyrrhizin showed significant reduced uptake of rohdamine 123 on V79 cells (Figs. 5 and 6).

4. Discussion

Recently we have investigated the antioxidant and anti-tumor activity of caffeic acid phenethyl ester (CAPE) analogous, and the result indicated that CAPE be acting as potential chemotherapic agent against oral cancer [36,37]. Similarly, quercetin and glycyrrhizin have drawn our attention because of its antioxidant, anti-tumor, and anti-inflammatory properties. To evaluate them as chemopreventive agents, we started to test the cytotoxicity of cadmium and AA on V79 cells. Under our investigation, the cytotoxicities of cadmium and AA on V79 cells were studied by the MTT or colony assay. According to our studies, both acute and chronic results showed a significant synergistic effect on cytotoxicity of co-exposure of cadmium and AA in V79 cells (Fig. 1). Similarly, at *Hprt* mutant assay, the results have also shown that the combined chronic genotoxicity of cadmium and AA be synergistic effect on V79 cells by colony assay.

After cytotoxicity and genotoxicity studies, we further investigated the formation of MDA is considered an index of lipid peroxidation that causes cell injury. For instance, the cytotoxicity and genotoxicity may be considered to be associated with oxidative stress, the lipid peroxidation and mitochondrial membrane potential assays were tested. Our observations may indicate that a mitochondrial permeability transition in response to co-exposure of cadmium and AA leads to plasma membrane damage or cell death. Although the mechanism of cytotoxicities or mutagenicities on the combined exposure of cadmium and AA is still not understood, it is well known that the protection of cells from oxidative damage can be accomplished through an antioxidant agent. Fortunately, our results assessed that reduced the mortality of V79 cells from oxidative damage by quercetin was two-folds than that of glycyrrhizin. Even though the mechanism of reducing the damage of plasma membrane by glycyrrhizin is still not understood, it should be different pathway from quercetin for protecting V79 cells.

In conclusion, based on the above assay results, combined treatment of cadmium and AA on V79 cells has shown a significant synergistic effect of cytotoxicity and genotoxicity. In addition, the superoxide radical species have been implicated in the increased cytotoxicity or mutagenicity of cadmium and AA on V79 cells by studies of lipid peroxidation formation

and uptake rhodamine 123. Moreover, the ability of quercetin and glycyrrhizin to scavenge free-radicals and block lipid peroxidation raises the possibility that they may act as protective factors against carcinogenesis, and it implies that quercetin is better than glycyrrhizin as chemopreventor against cytotoxicity and genotoxicity on co-exposure of cadmium and AA in V79 cells. Furthermore, quercetin is consistent with structure and activity relationship that the aryl units contain at least one aryl ring required *o*-bis-hydroxylation for significant inhibitory potency of antioxidants. Therefore, further investigation should address how cadmium and AA affect cytological activities in normal cells. Further in vivo assays are currently underway to evaluate the efficacy of quercetin and glycyrrhizin as chemopreventive agents against carcinogenesis.

Acknowledgements

The authors are indebted to Professor Ruey-Hseng Lin for the generous gift of V79 cells. For financial support, we thank the National Science Council of the Republic of China (Research Grant NSC 87-2113-M-040-001 and NSC 89-2113-M-018-003).
